

Progress Towards Understanding the Global and Structural X-Ray Properties of Galaxy Clusters

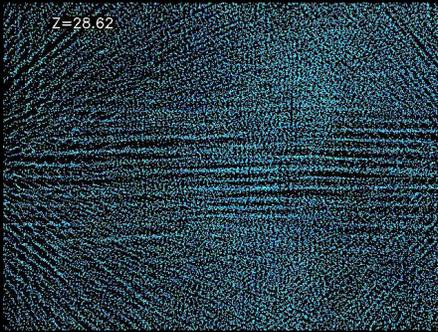

**THE IGM RECIPE BOOK:
SPECIAL TREATS SECTION
"COOKING UP A HEADY BREW OF ICM"**

Ian McCarthy (UVictoria)

Mike Balogh (UWaterloo)	Arif Babul
Greg Poole (UVictoria)	Director, C4
Gil Holder (McGill)	University of Victoria
Neal Katz (UMass)	Leverhulme Visiting
Tom Quinn (UWashington)	Professor
J. Dalcanton (UWashington)	Oxford/Durham
L. Williams (UMinnesota)	

First, start with dashes, pinches and fistfuls of dark matter, throw them together, and stir...

❖ Dark matter halos forms hierarchically Movie: A. Kravtsov

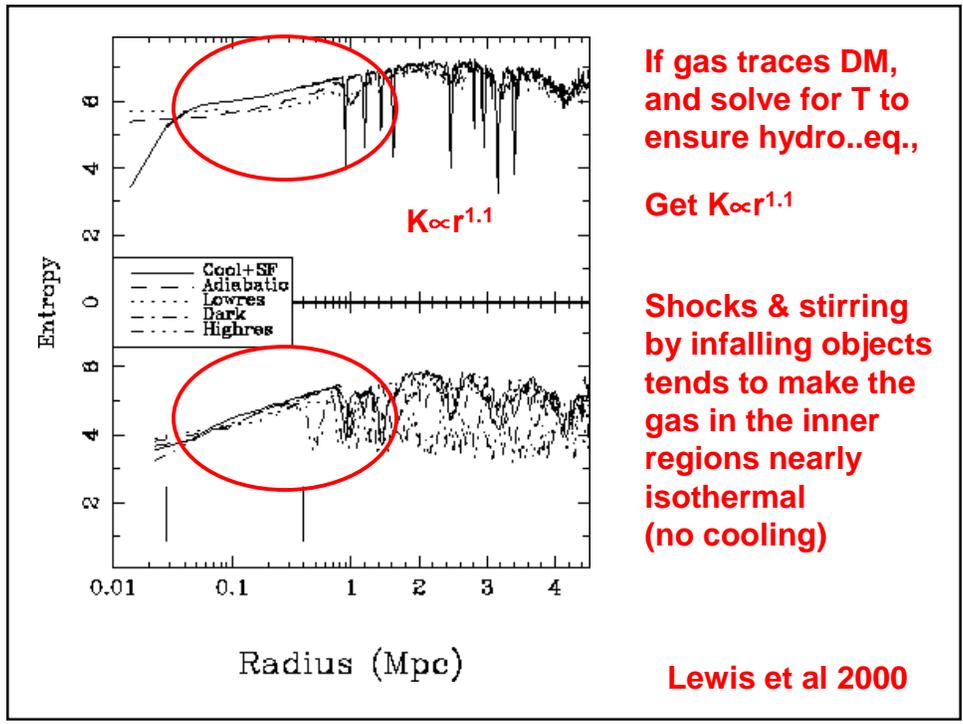

$$\rho(r) = \rho_0 \left(\frac{r}{r_s} \right)^{-1} \left(1 + \frac{r}{r_s} \right)^{-2} \quad \frac{\rho(r)}{\sigma^3} \propto r^{-15/8}$$

Progress Towards Understanding the Global and Structural X-Ray Properties of Galaxy Clusters

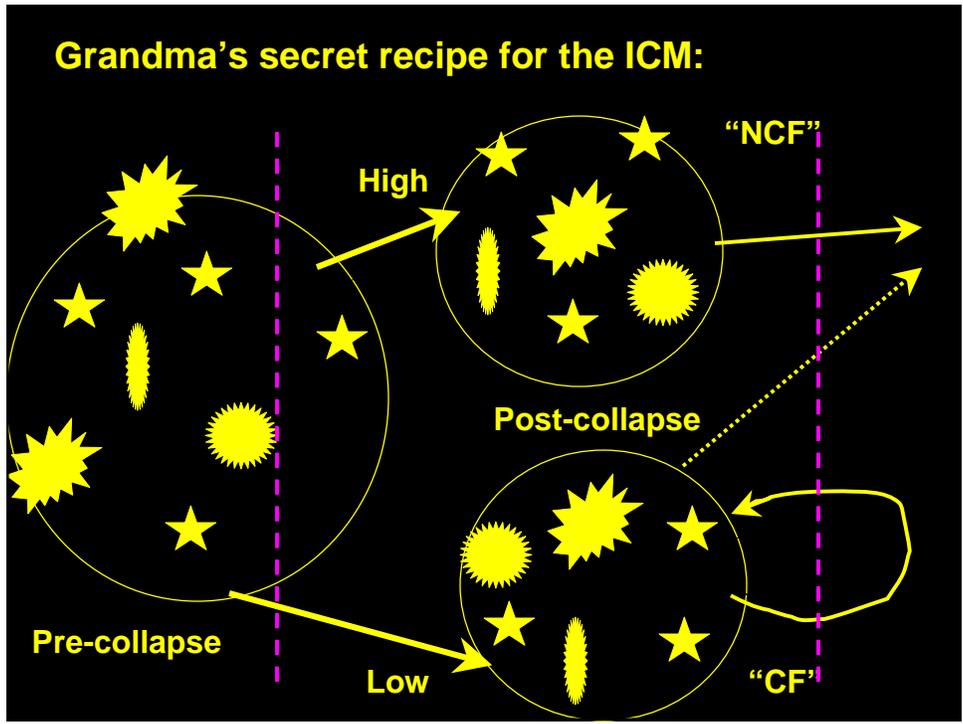

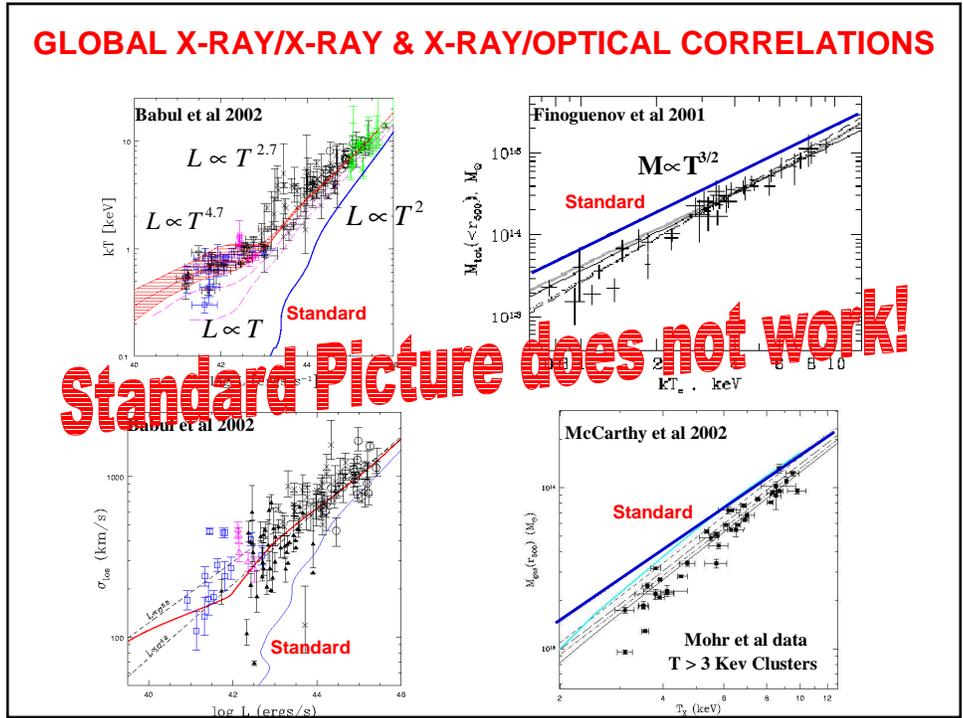

First, mix in gas in proportion. Do not stop stirring, otherwise...

❖ In the standard model, gas falls in with dark matter and in the absence of any energy transport, will trace the dark matter
 → entropy due to accretion:

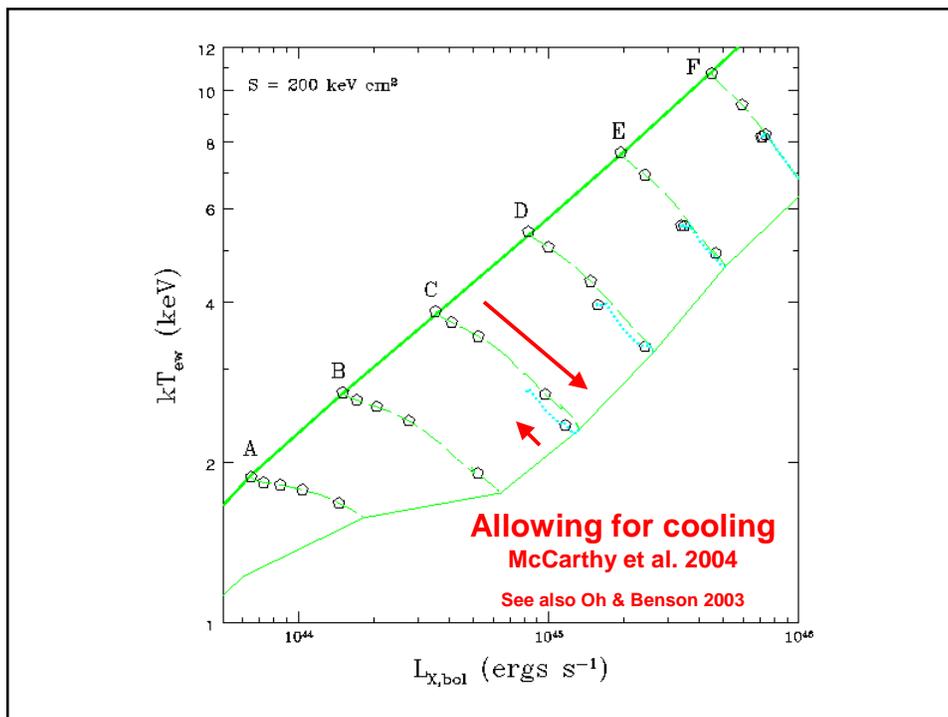

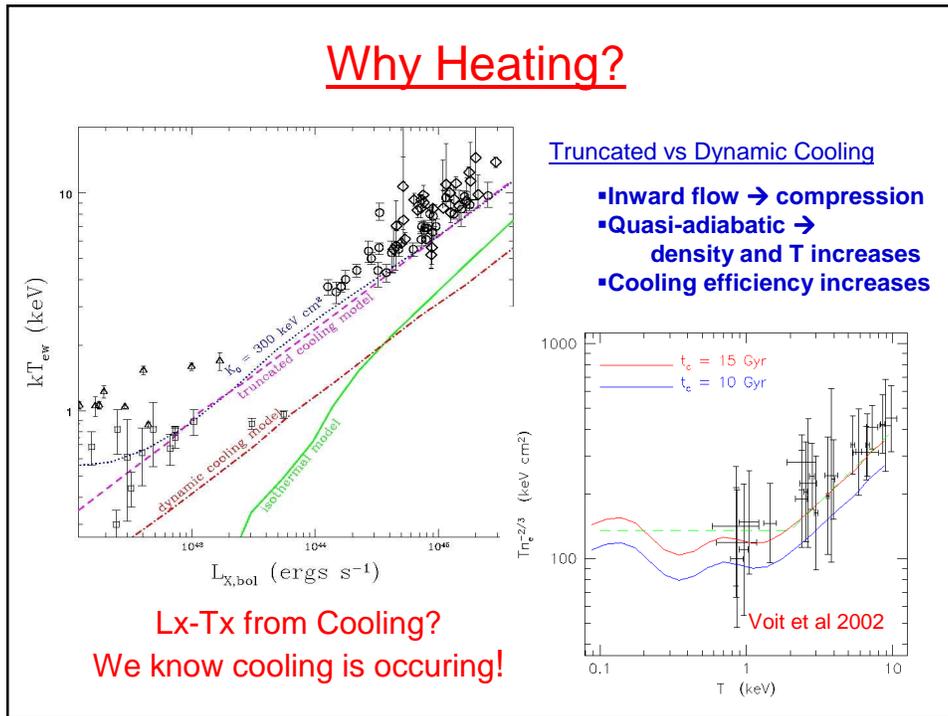

$$\frac{\rho(r)}{\sigma^3} \propto r^{-15/8} \Rightarrow \frac{KT}{n_e^{2/3}} \propto r^{1.25} \quad [1.1-1.2]$$

Why consider preheating as a starting point?

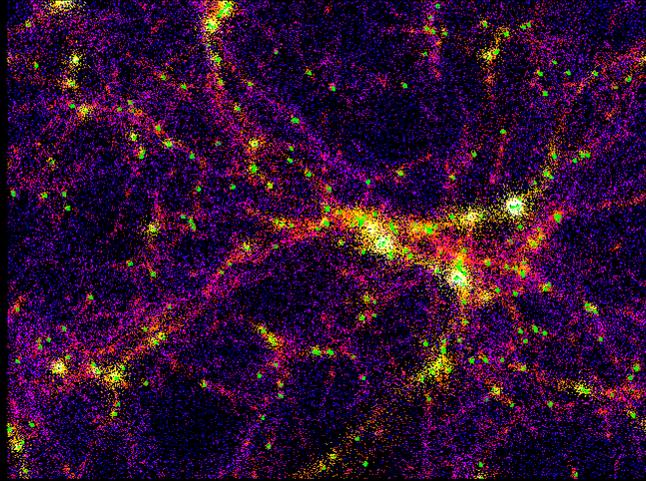

Epoch of quasars and galaxy formation precedes clusters → outflows will heat the surrounding IGM

AGN feedback is necessary to quench growth of brightest ellipticals, otherwise conflict galaxy luminosity function.

Progress Towards Understanding the Global and Structural X-Ray Properties of Galaxy Clusters

Regions of highest energy injection will coincide
With regions of high galaxy density:

Galaxy Formation at $z=2$: Weinberg et al.

POSTULATE:

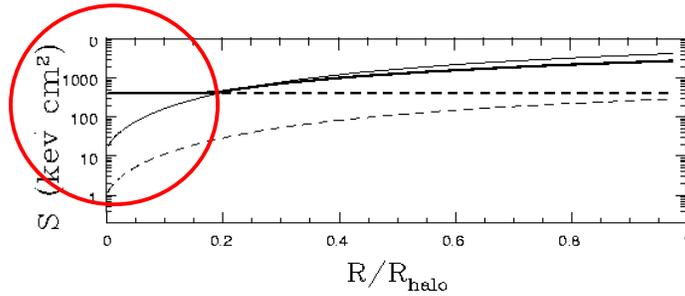

There is a variation in the heating of the gas from
cluster-to-cluster → range of “minimum entropy”

- ❖ variations in the BH energy output
- ❖ star-formation histories
- ❖ timing

Progress Towards Understanding the Global and Structural X-Ray Properties of Galaxy Clusters

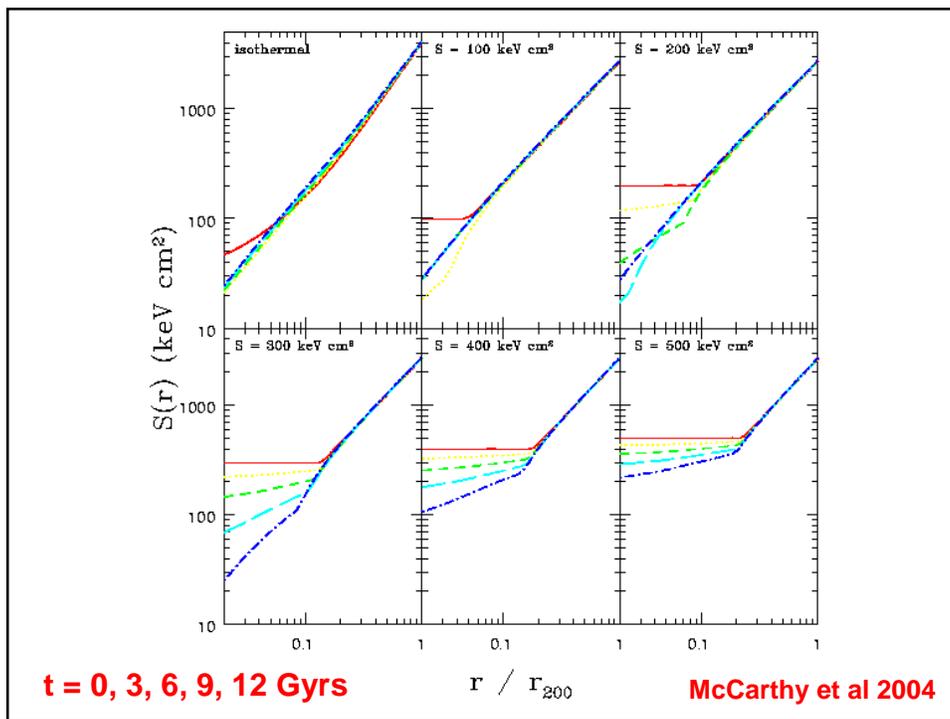

Entropy injection will move the lower entropy gas onto higher adiabat

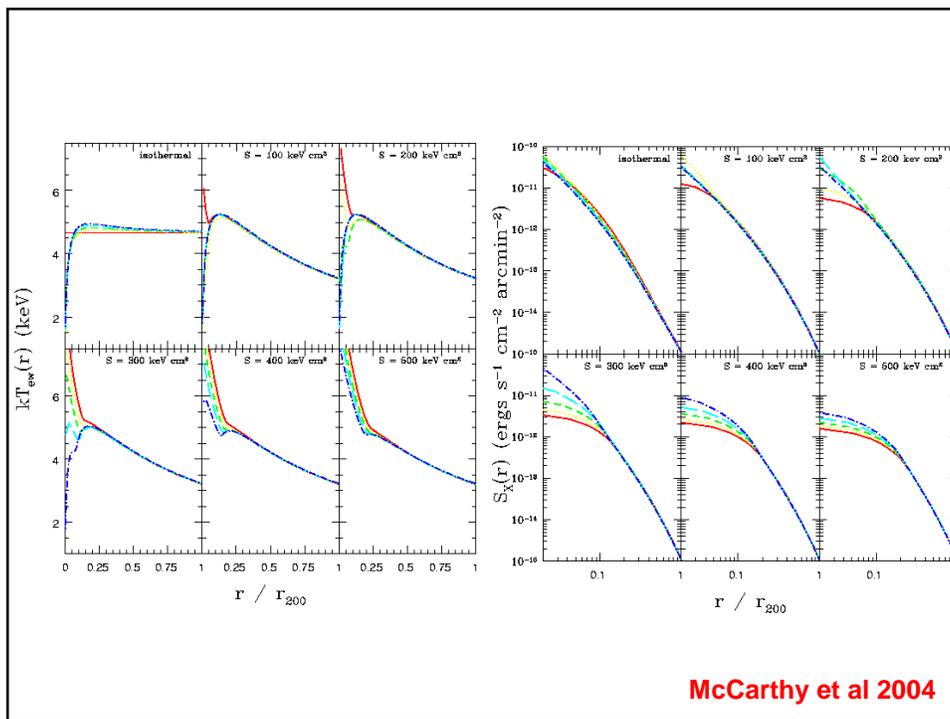

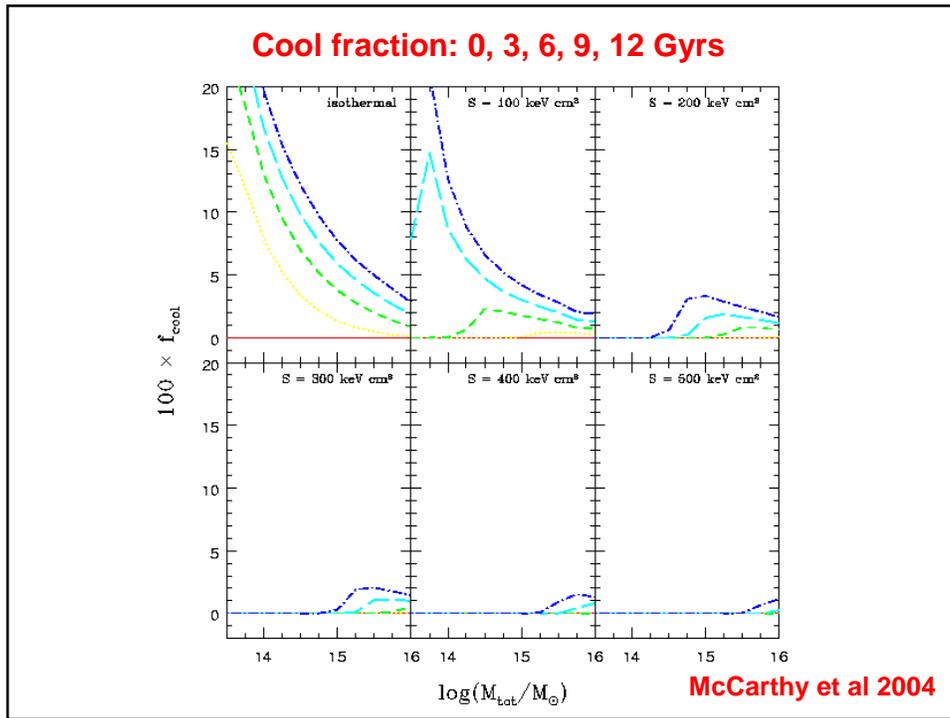

Gas in the clusters will also lose energy via cooling

The impact of cooling will depend on:

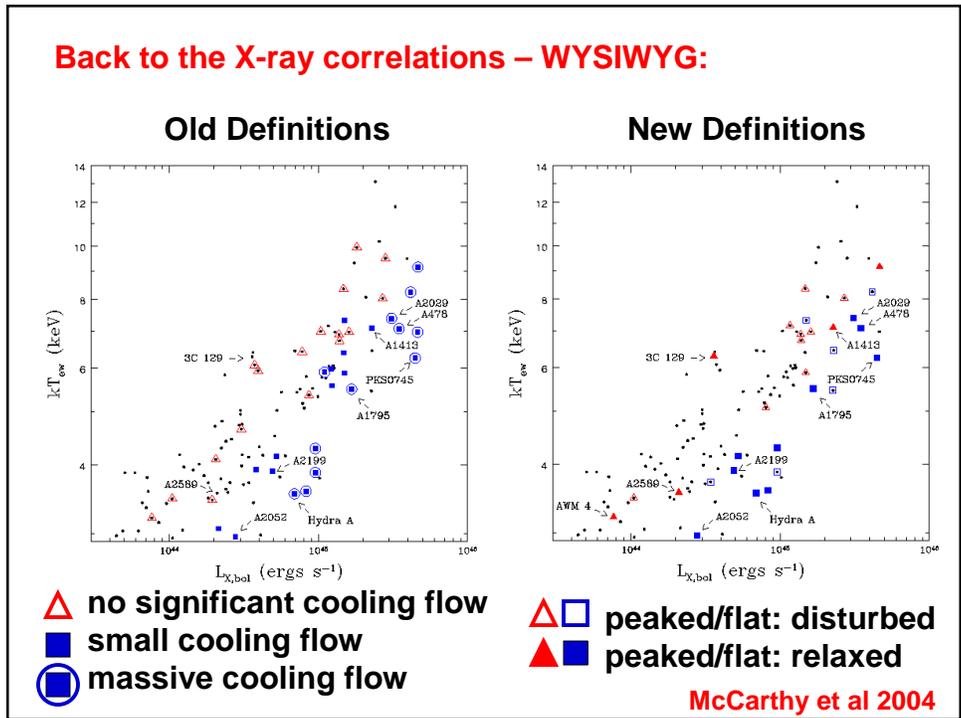

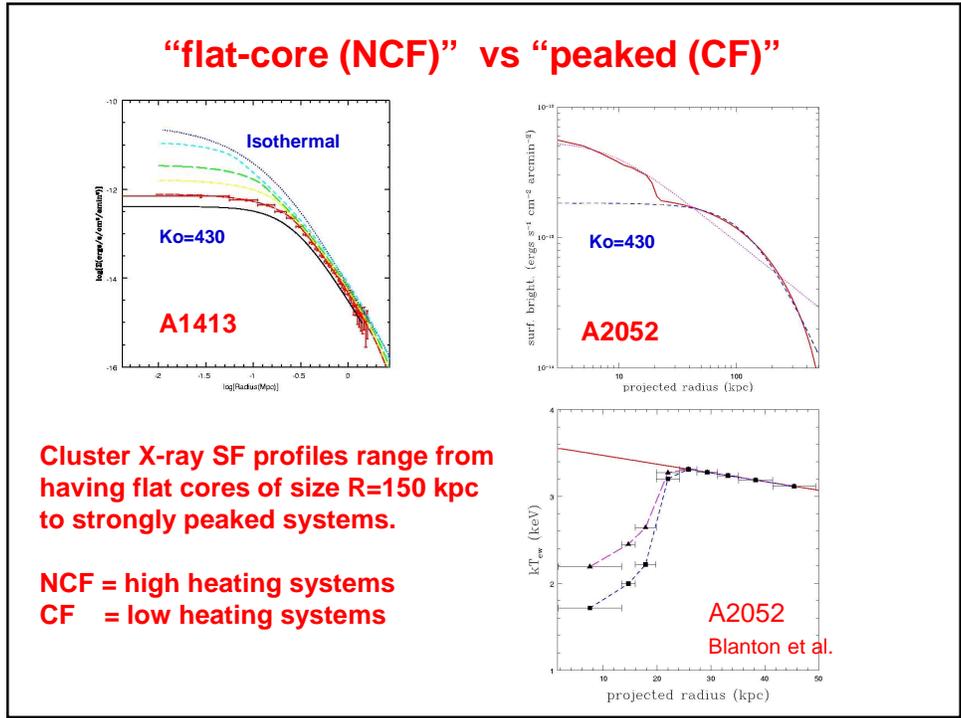

- (a) “preheating” level**
- (b) time available for cooling**

In our picture, the two classes of clusters are the result of variations in the initial entropy injection.

Traditionally, the tacit belief is that NCFs are effectively CF systems that have been stirred up by mergers.

This is based on anecdotal claims that NCF systems tend to have substructure. This is true, but there are also NCF systems that have *NO* visible substructure and which really do look relaxed. There are also CF clusters actively assimilating mergers (Perseus).

Theoretical studies of mergers and their effects on central regions of clusters are few and far in-between, and the outcomes are confusing.

WORK IN PROGRESS

- 3:1 or greater – fraction of these is rare.
- During disruption, systems look like NCF for ~2 Gyrs.

Conclusion: Heating and Cooling

- ✓ Heating at the level of $S_{\min} \sim 200 \text{ keV cm}^2$ is needed to prevent excessive cooling of baryons
- ✓ Radiative cooling tends to establish $S \sim r^{1.1}$
- ✓ Depending on amount of entropy injection and the time elapsed since entropy injection, the model can account for variations in the internal (structural) properties of clusters such as X-ray surface brightness profiles and cluster temperature profiles
 - mild entropy ($S \sim 200$): CF (peaked)
 - high entropy ($S \sim 400$): NCF (flat-core)
- ✓ NCF clusters: the “heating” vs “merger” hypotheses

Conclusion: Heating and Cooling

- ✓ Variations in level of entropy injection and time since this event can account for the dispersion in the M-T, L-T relations, as well as the the distribution in the size of the X-ray core radius.
- ✓ This picture suggest a direct correlation between the cluster's entropy profile and its location on the M-L, L-T and R_c - β plots.
- ✓ Model is testable! A preliminary study of Chandra and XMM-Newton data supports this assertion.
Available vs anticipated data
