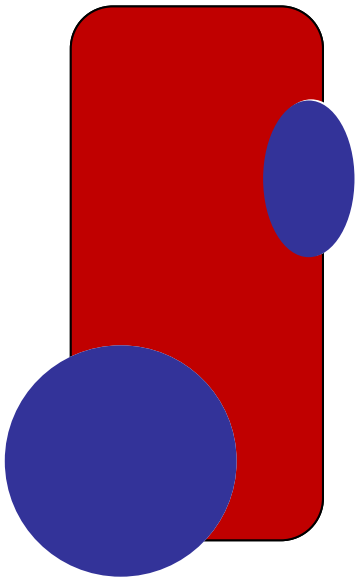
Protein Allostery

Durham University

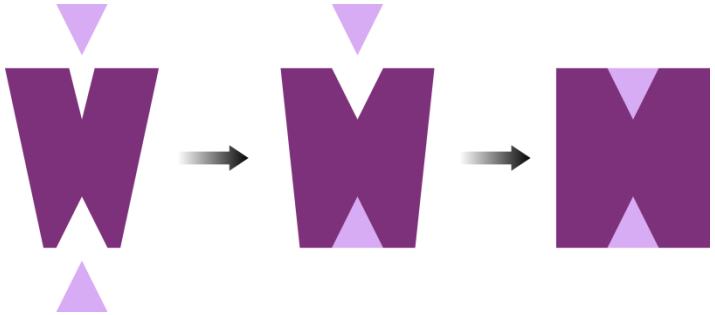
- Effect of binding one molecule on a second binding



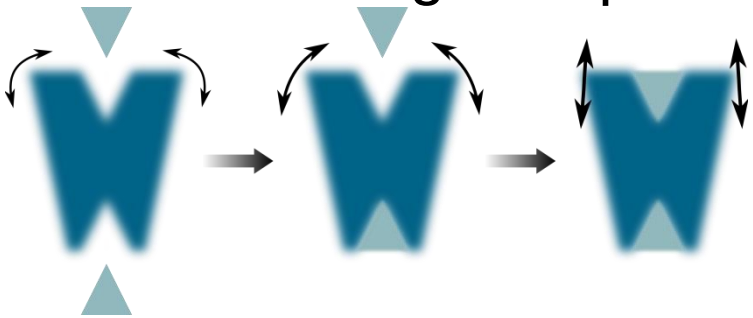
- Central role in biochemical pathways
  - Binding an activator causes binding to DNA
  - Binding a ligand enhances or inhibits binding elsewhere to regulate a process

Allosteric Binding

- Classically explained by conformational change



- Free energy contributions from changes in protein vibrations



$$\Delta G = \Delta H - T\Delta S$$

Allosteric Binding – example of CAP

- Catabolite Gene Activator Protein (CAP)

$$\Delta\Delta G = \Delta G_2 - \Delta G_1$$

- Negative cooperativity

$\Delta\Delta G > 0$

(affinity for binding 2nd ligand is reduced)

- Positive cooperativity

$\Delta\Delta G < 0$

Catabolite Activated Protein (CAP) homodimer shows negative co-operativity between two identical binding sites for cyclic AMP (cAMP) without a change in structure

Aims of this talk

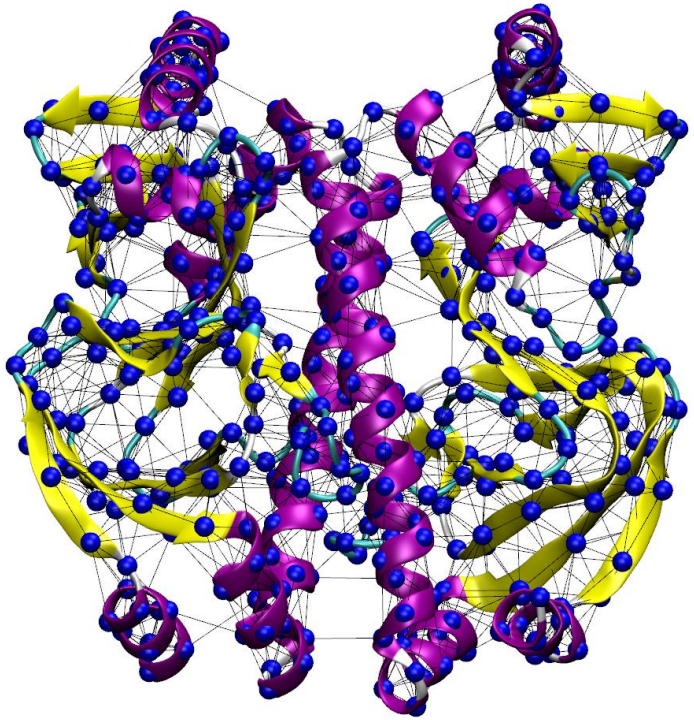
Durham University

1. Use multi/many-scale models to investigate dynamic allostery for (the protein dimer) CAP
   - Elastic Network Model insights
   - Super-coarse-grained models
   - Atomistic Models
2. Use the models to show how we can control dynamic allostery by selected mutation
   - hence control dynamic landscape of a protein
   - provide a new route for drug design?
3. Point to some other ways in which proteins have evolved to harness dynamic pathways

Elastic Network Model (ENM)

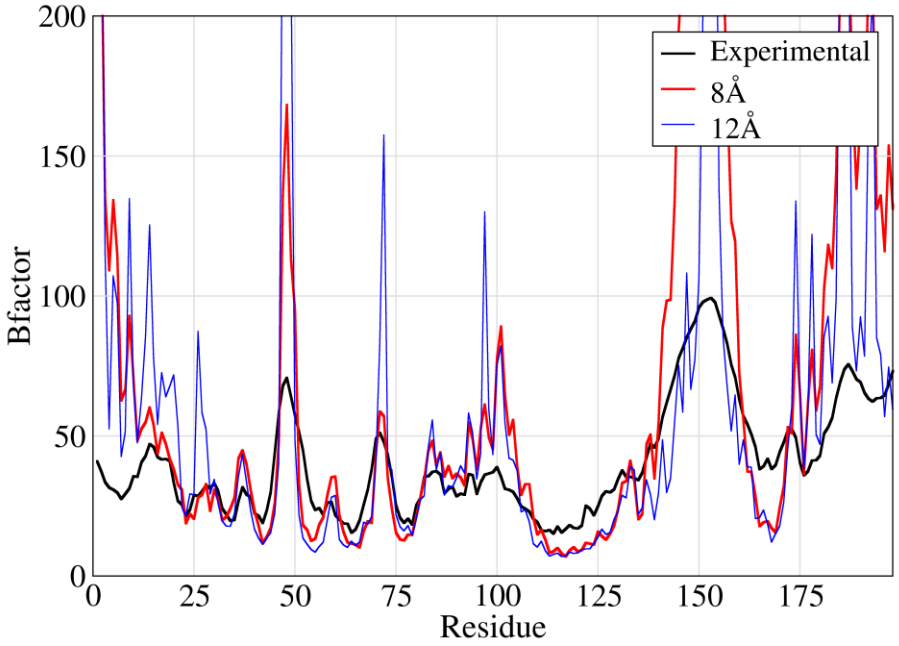
- Join C_α atoms with Hookean springs
- Diagonalize mass-weighted Hessian matrix
- Eigenvectors – normal modes
- Eigenvalues – frequencies
- Low frequency modes most important for motion

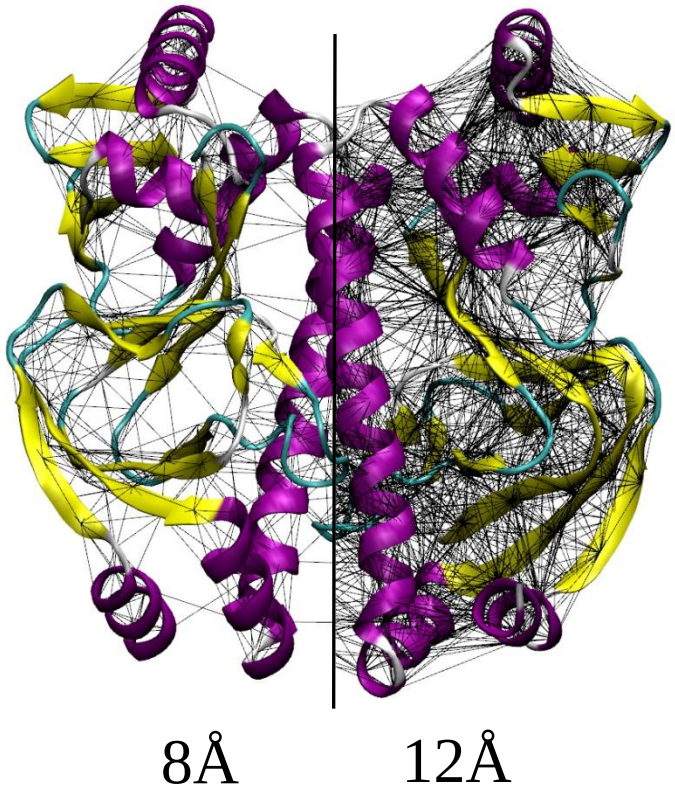
Catabolite Gene Activator Protein (CAP)



$$V_{ij} = \begin{cases} \frac{k_{ij}}{2}\left(r_{ij} - R_{ij}\right)^2 & R_{ij}^2 \leq R_c^2 \\ 0 & R_{ij}^2 > R_c^2 \end{cases}$$

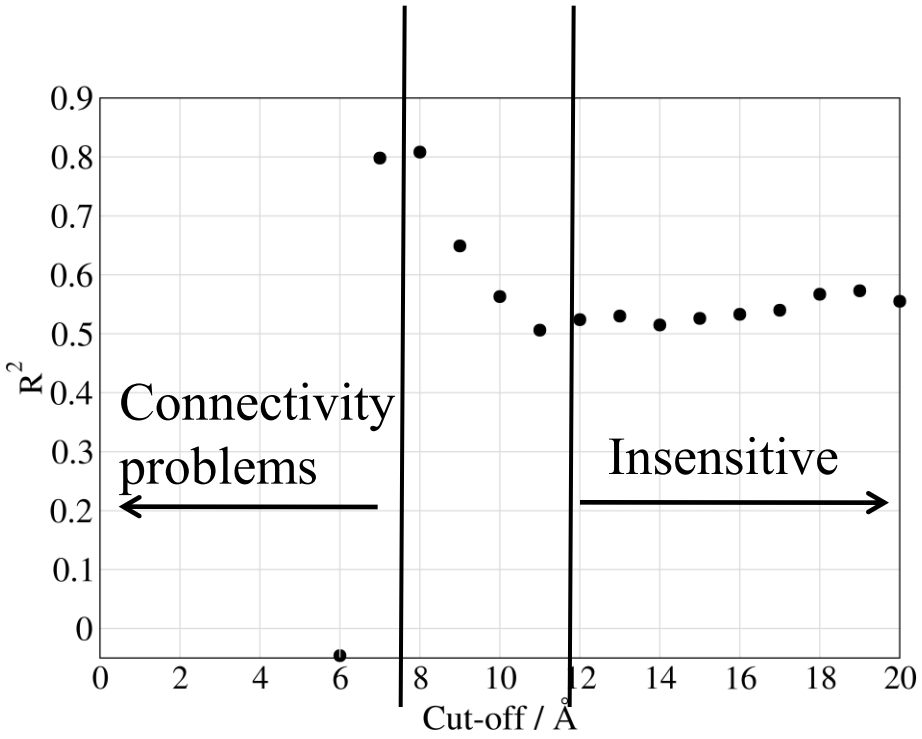
ENM cutoff

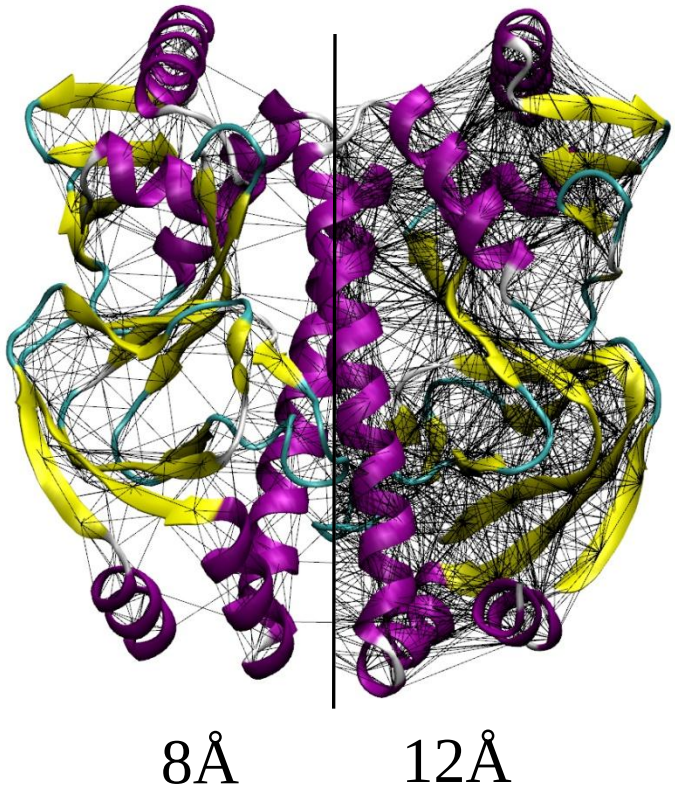




- Smaller cut-off is better

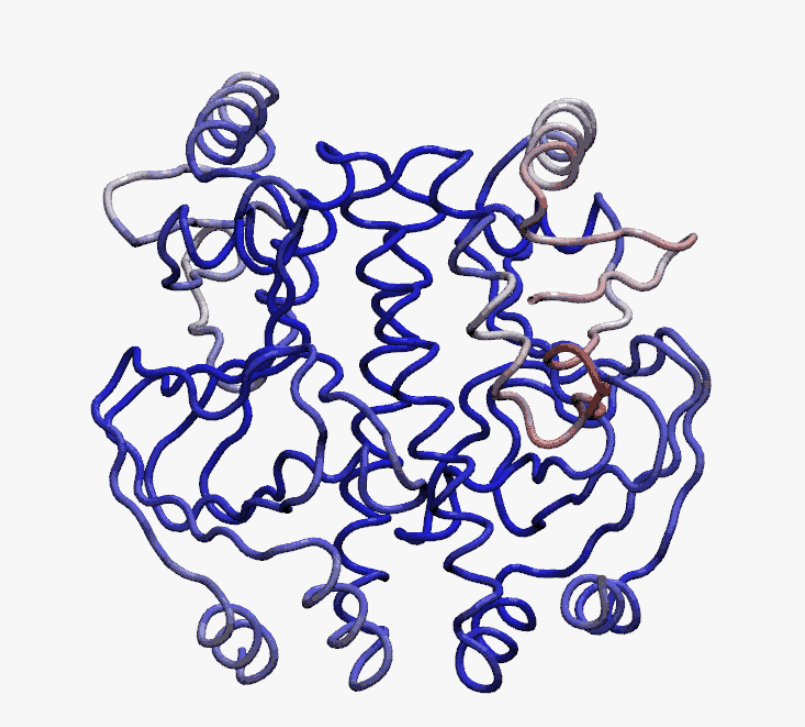
ENM cutoff

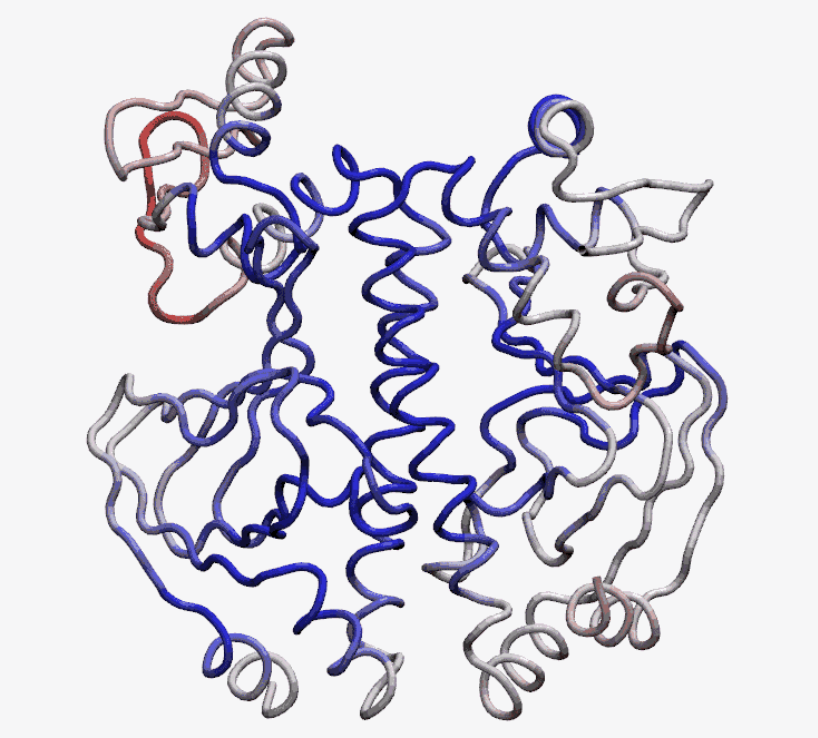




- Smaller cut-off is better

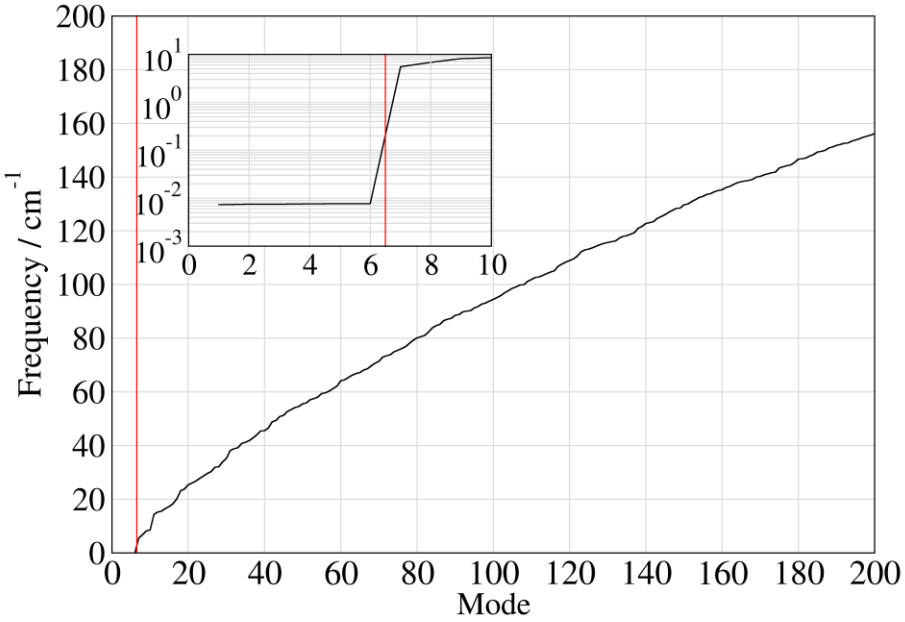
Modes



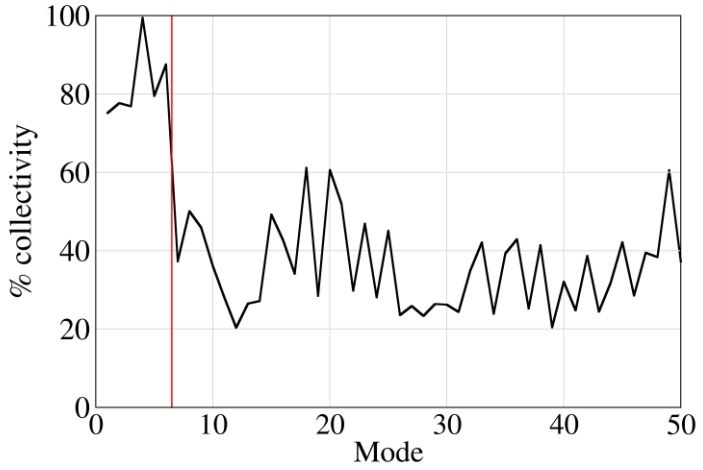


Note: - movements of the whole protein
- importance of the strength of hydrophobic interactions between helices

Variation of Mode Frequency



- Large number of contributing modes
- Low frequency modes involve whole protein



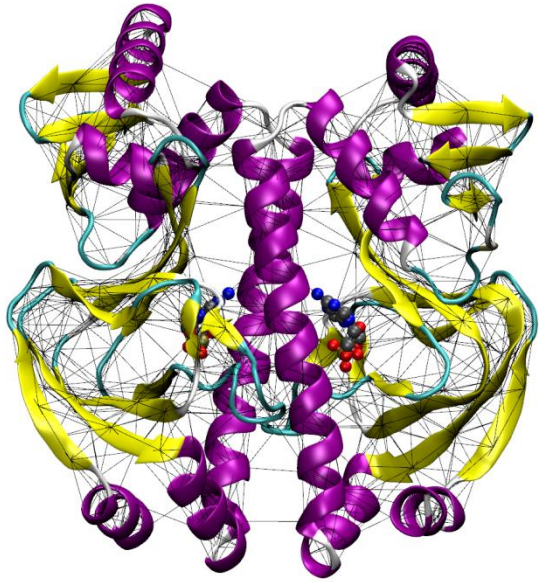
Calculating Allostery with the ENM

Durham University

$$\mathrm{CAP_{apo}} + 2\mathrm{cAMP} \underset{K_{1,\mathrm{unbind}}}{\overset{K_{1,\mathrm{bind}}}{\rightleftharpoons}} \mathrm{CAP_{holo1}} + \mathrm{cAMP} \underset{K_{2,\mathrm{unbind}}}{\overset{K_{2,\mathrm{bind}}}{\rightleftharpoons}} \mathrm{CAP_{holo2}}$$

- Experimental Allostery coefficient,

$$\frac{K_2}{K_1} = \frac{K_{2,\mathrm{unbind}}}{K_{1,\mathrm{unbind}}} = \frac{K_{1,\mathrm{bind}}}{K_{2,\mathrm{bind}}}$$



- Calculate vibrational free energy

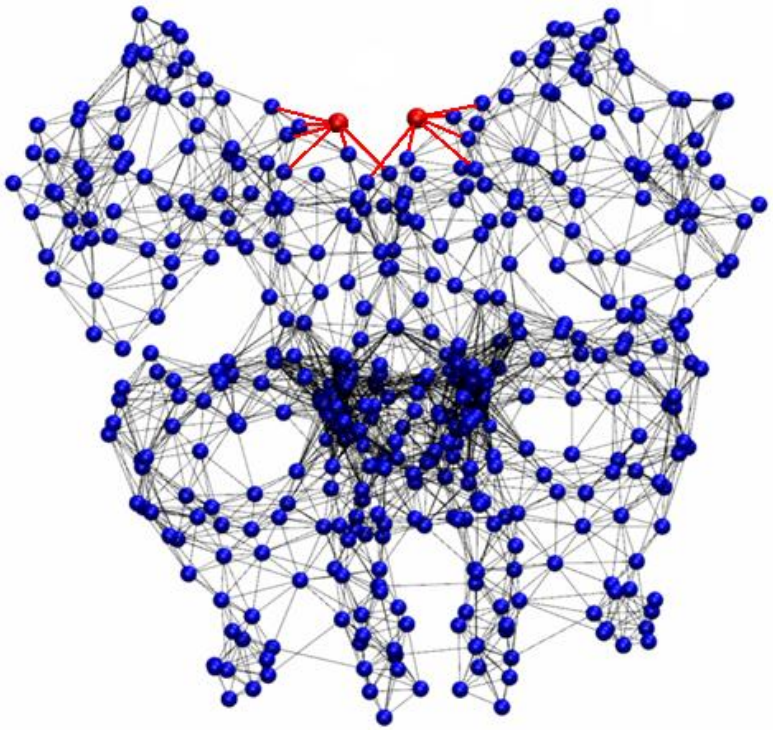
$$\Delta\Delta G = \left(\Delta G_{\mathrm{holo2}} - \Delta G_{\mathrm{holo1}}\right) - \left(\Delta G_{\mathrm{holo1}} - \Delta G_{\mathrm{apo}}\right) = \frac{kT}{2} \ln\left(\frac{\left|\mathrm{H}_{\mathrm{holo\,2}}\right|\left|\mathrm{H}_{\mathrm{apo}}\right|}{\left|\mathrm{H}_{\mathrm{holo1}}\right|^2}\right)$$

- Determine K_2/K_1

ENM predicts $K_2/K_1 > 1$ negative cooperativity
(reduced affinity – as seen experimentally)

Protein Mutations in the ENM

- Mutations represented by varying residue spring constant
- Can investigate sensitivity of vibrational contribution to $\Delta\Delta G$



CAP mutations

Durham University

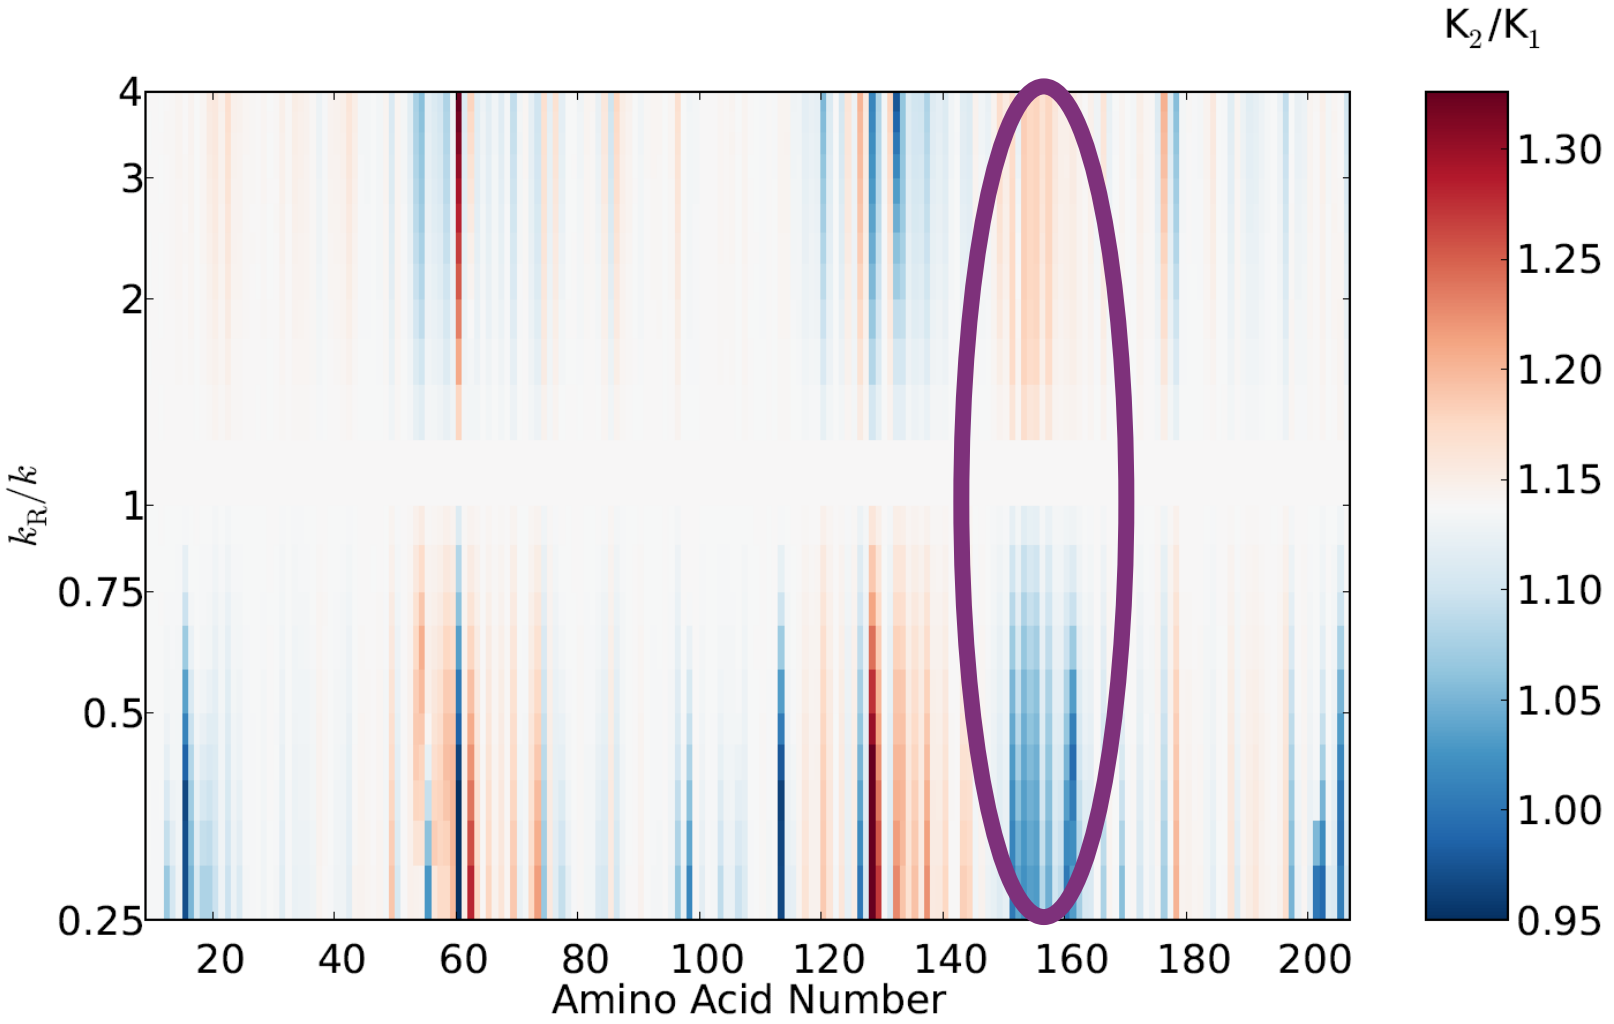
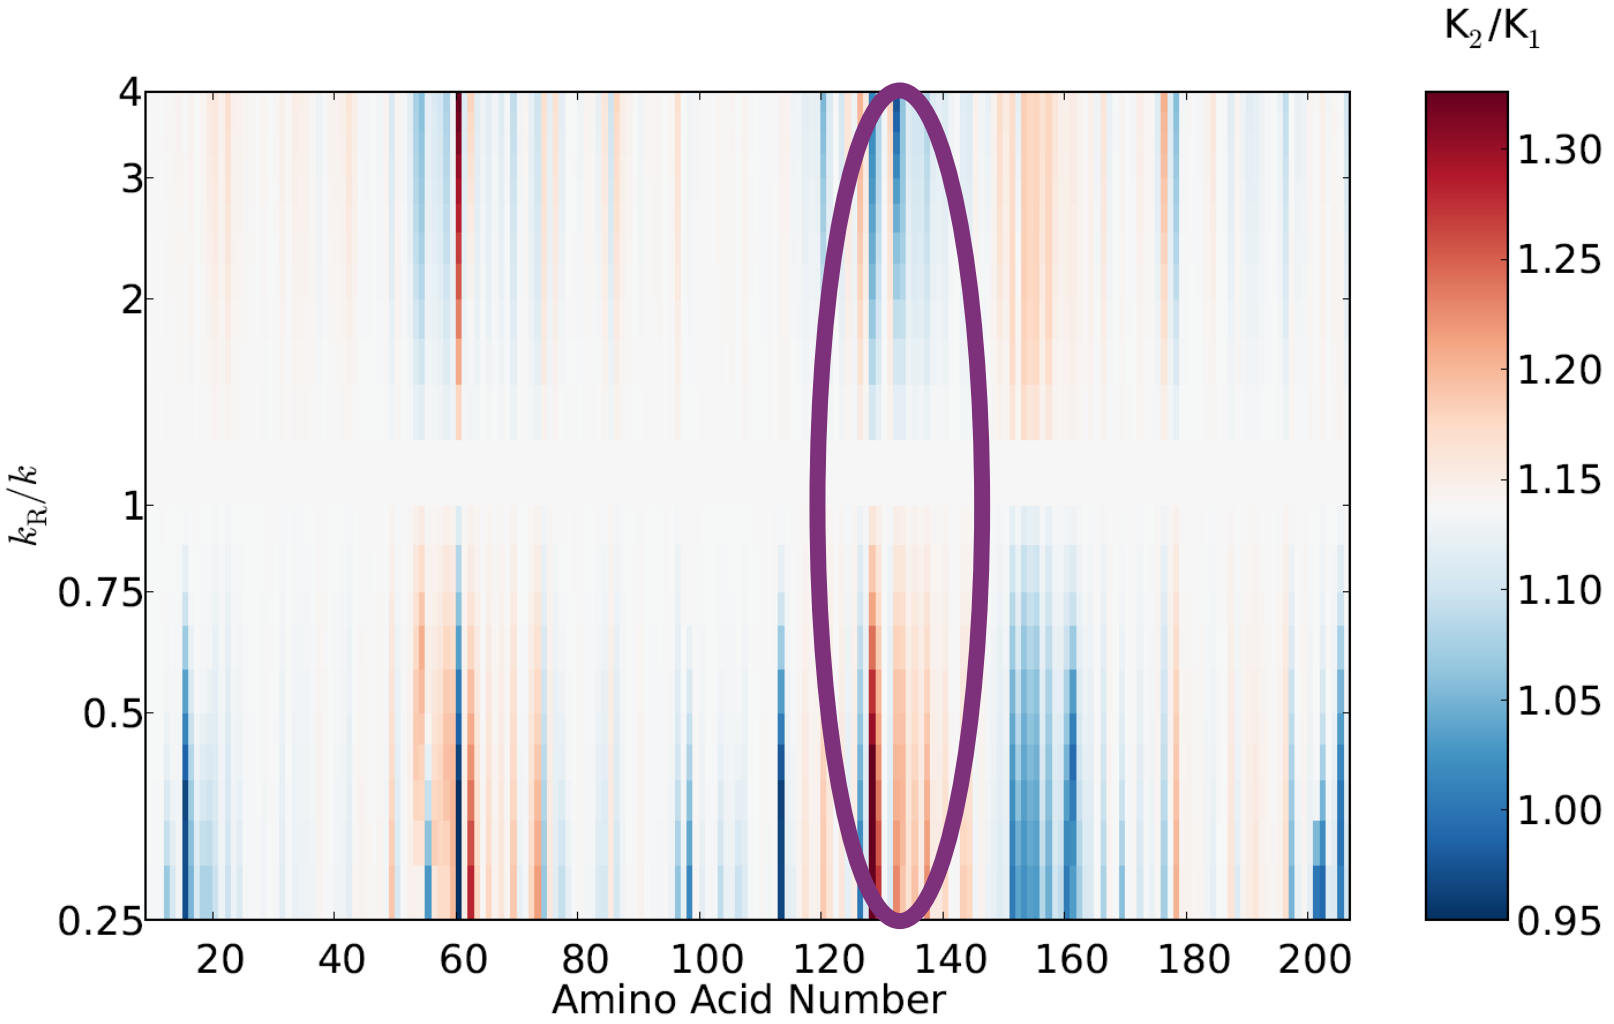
Protein Engineering

Durham University

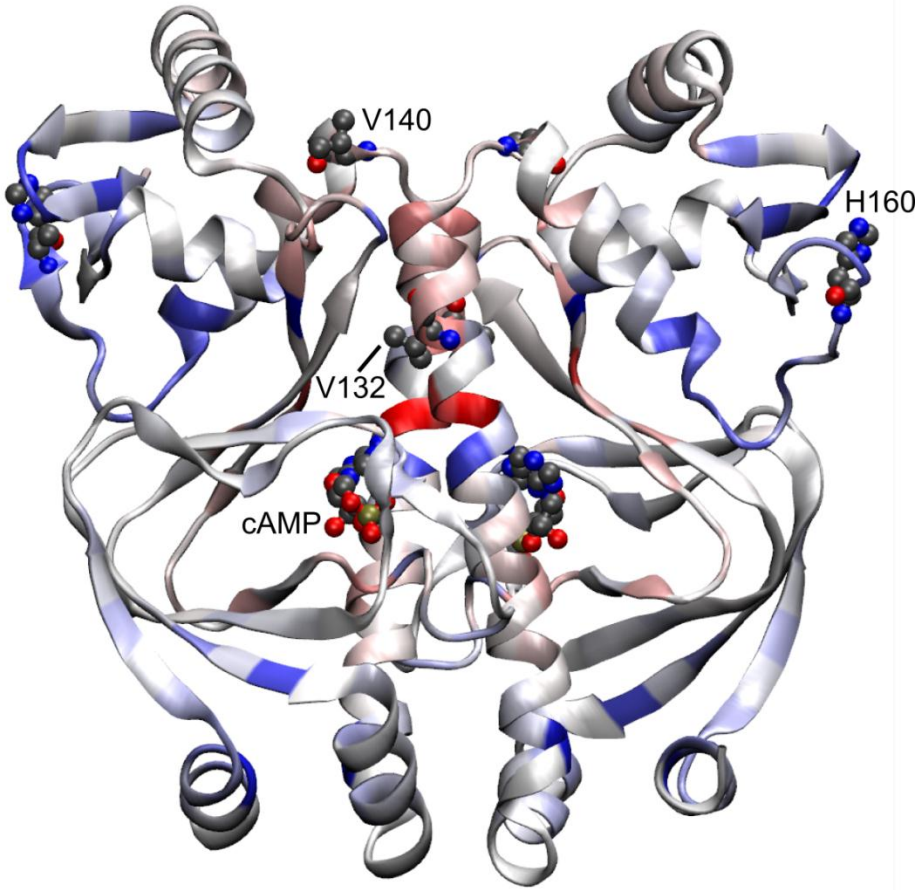


Protein Engineering

Durham University



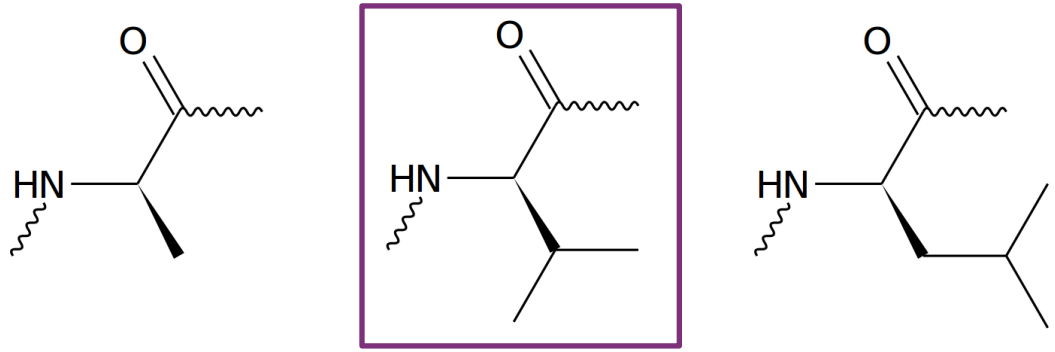
Protein Engineering with the ENM



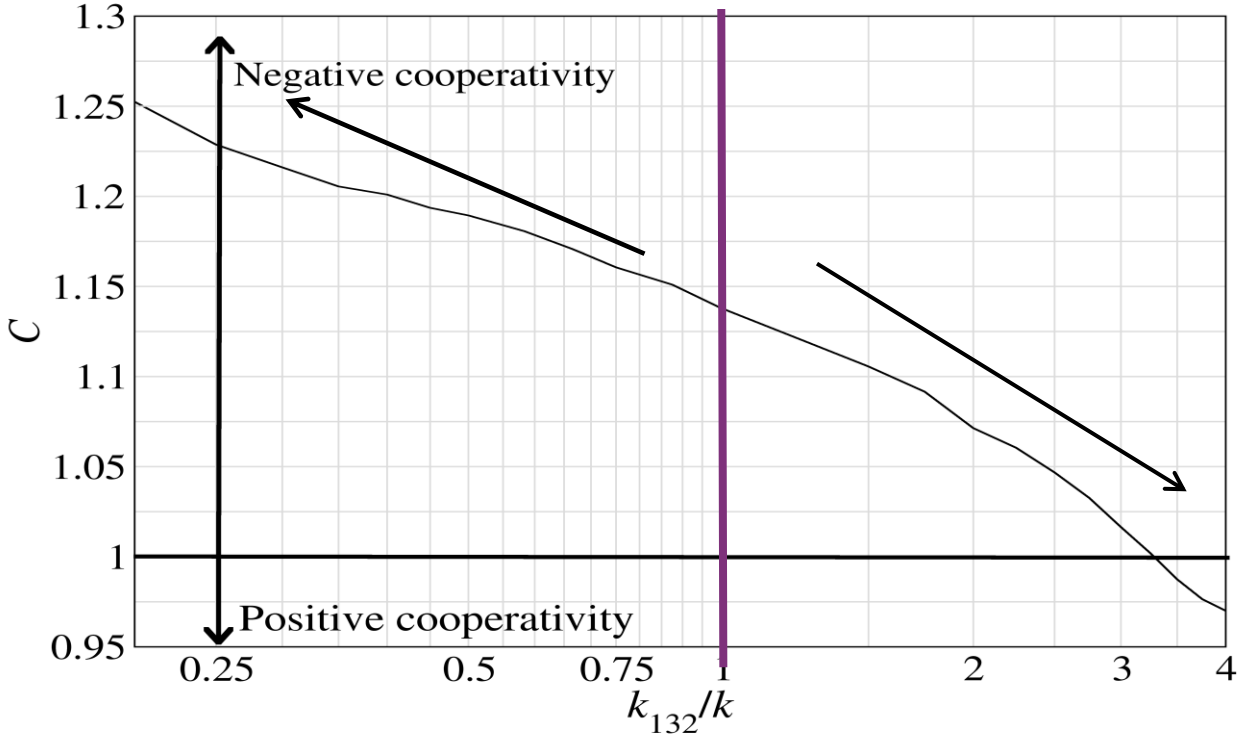
Decreasing stiffness in red regions leads to increased –ve cooperativity

Decreasing stiffness in blue regions leads to +ve cooperatvity

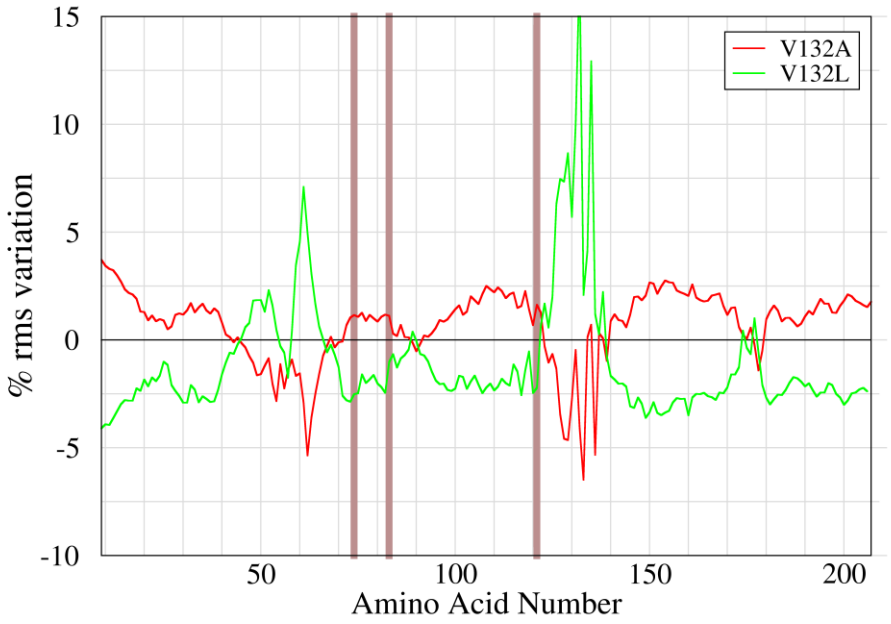
Protein engineering in practice - Variation in V132



Alanine Valine Leucine



Motion Variation



- At the dimer interface changes in hydrophobic interaction have big effect on motion across protein
- Mutation to alanine or leucine have opposite effects

cAMP affinities for proteins

- The ratio of the second to first dissociation constants for cAMP (K_2/K_1) for wild type and mutant CAP proteins

	CAP protein	K_2/K_1 (ENM)	K_2/K_1 (ITC)		
☺	Wild Type	1.13	1.6	✓	
☺	V132A/*k*=0.25	↑	↑	✓	
☺	V132L/*k*=0.25	↓ +ve	↓ +ve	✓	
☺	H160L/*k*=0.25	↑	↑	✓	H-bond removal
☯	V140A V140/*k*=0.25 V179/*k*=4	↓ +ve	↓ +ve	✓	X-ray shows conformational change
☺	V140L/*k*=4	↑	↑	✓	

☺High resolution X-ray – confirm no change in protein structure

Super-Coarse Graining

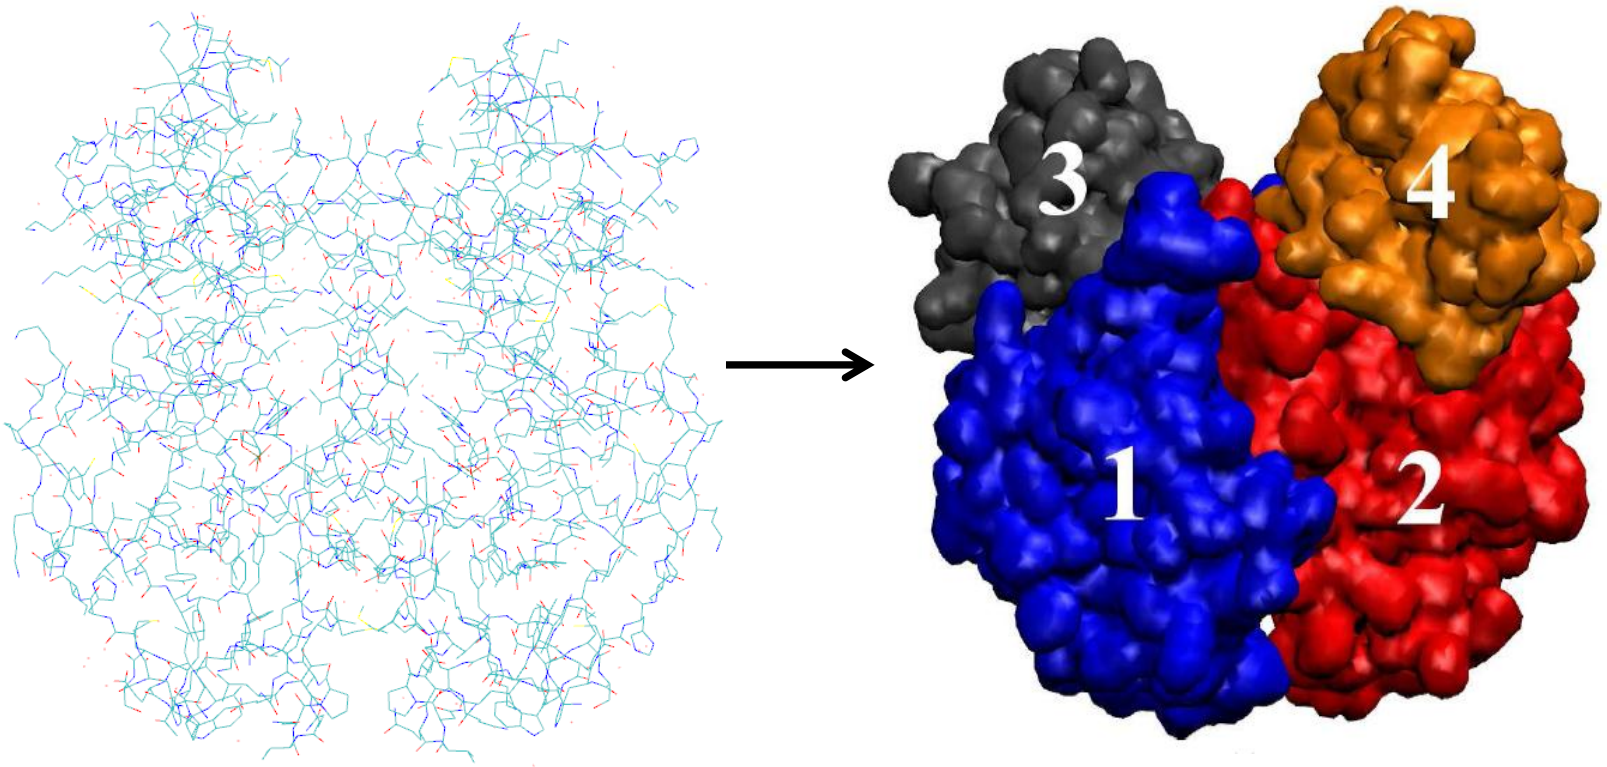
Durham University

- ENM provides valuable insights
- ENMs can predict motion and allostery

But….

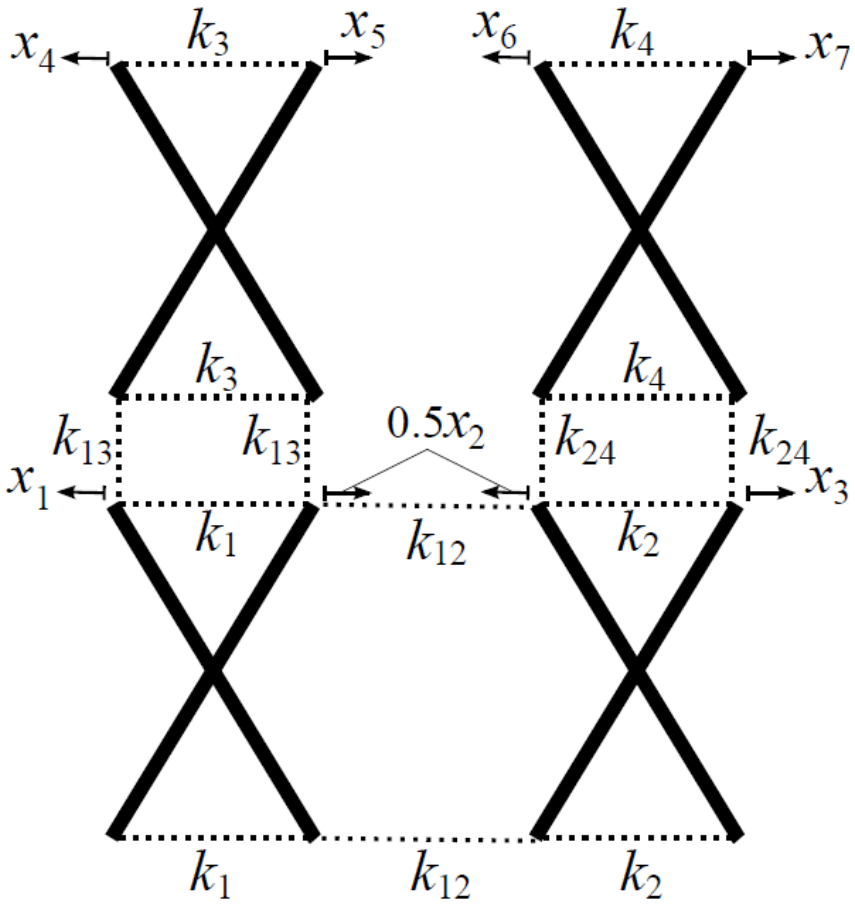
- A 3N x 3N interaction matrix to work with
- & it looks like there are some generic features that could be captured by a simpler model

Rotational Translational Block method



- Now (4 x 6) x (4 x 6) matrix – interactions easier to identify

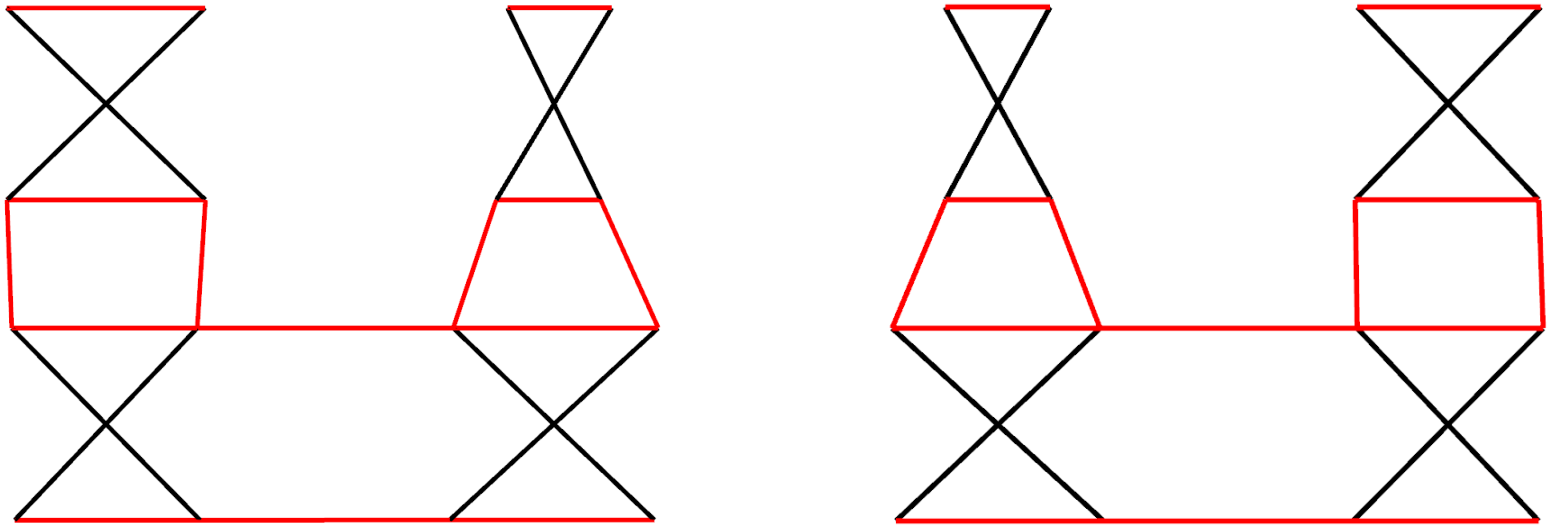
Super-Coarse Grain Models



- CAP monomer approximated as 4 'scissor' domains
- Internal spring constants $k_1 = k_2$, $k_3 = k_4$
- 3 independent coupling spring constants k_{12}, k_{13}, and k_{24}

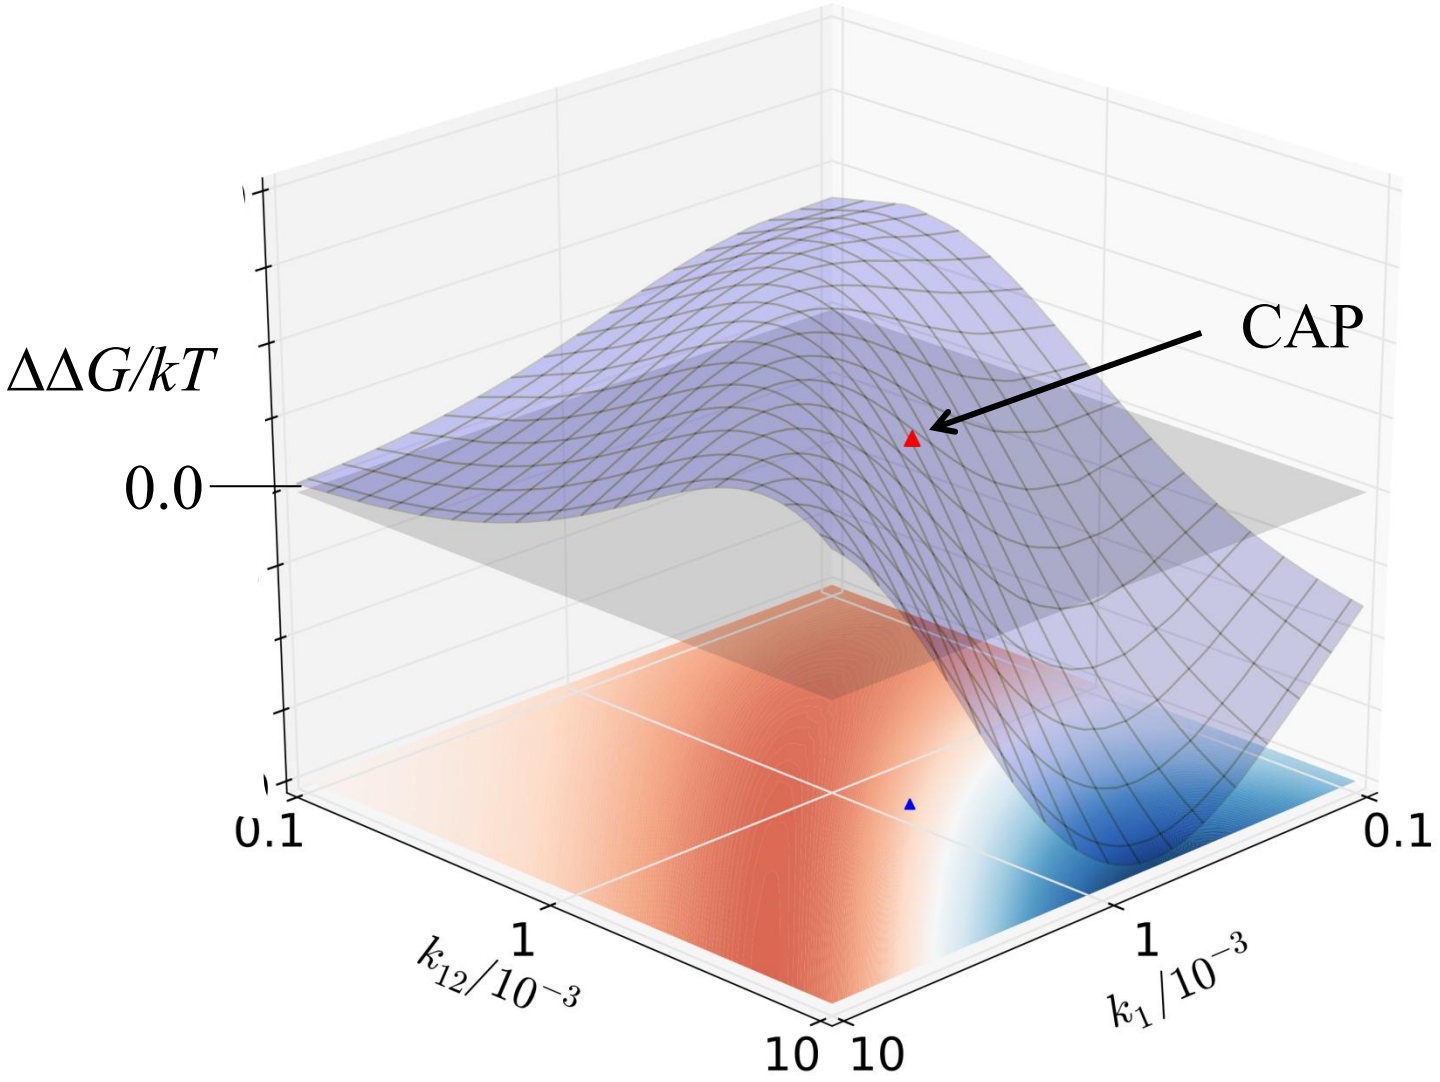
Super-Coarse Grained Models

Durham University



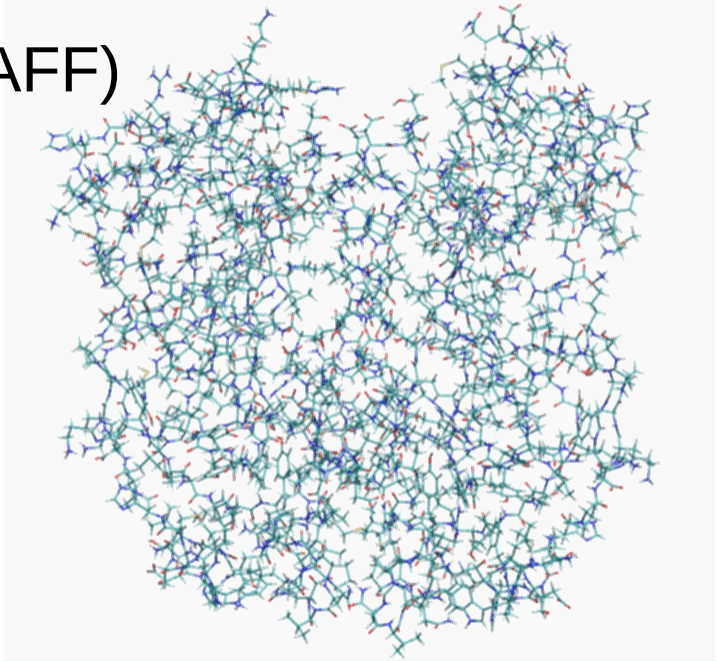
Super Coarse-Grained CAP

Durham University



Atomic Simulations

- Full atomistic simulations in water (AMBER, 2 fs time step, ff99SB/GAFF)
- 200+ ns molecular dynamics
- 6457 protein atoms
  - 401 amino acids
  - 10297 water molecules



$$V = \sum_{\text{bonds}} \frac{1}{2} k_b (l - l_0) + \sum_{\text{angles}} \frac{1}{2} k_a (\theta - \theta_0) + \sum_{\text{torsions}} \frac{1}{2} V_n \left(1 + \cos(n\varphi - \gamma)\right)$$

$$+ \sum_{i,j} \frac{1}{4\pi\varepsilon\varepsilon_0} \frac{q_i q_j}{r_{ij}} + \sum_{i,j} 4\varepsilon_{ij} \left(\left(\frac{\sigma_{ij}}{r_{ij}} \right)^{12} - \left(\frac{\sigma_{ij}}{r_{ij}} \right)^{6} \right)$$

Atomistic Simulations

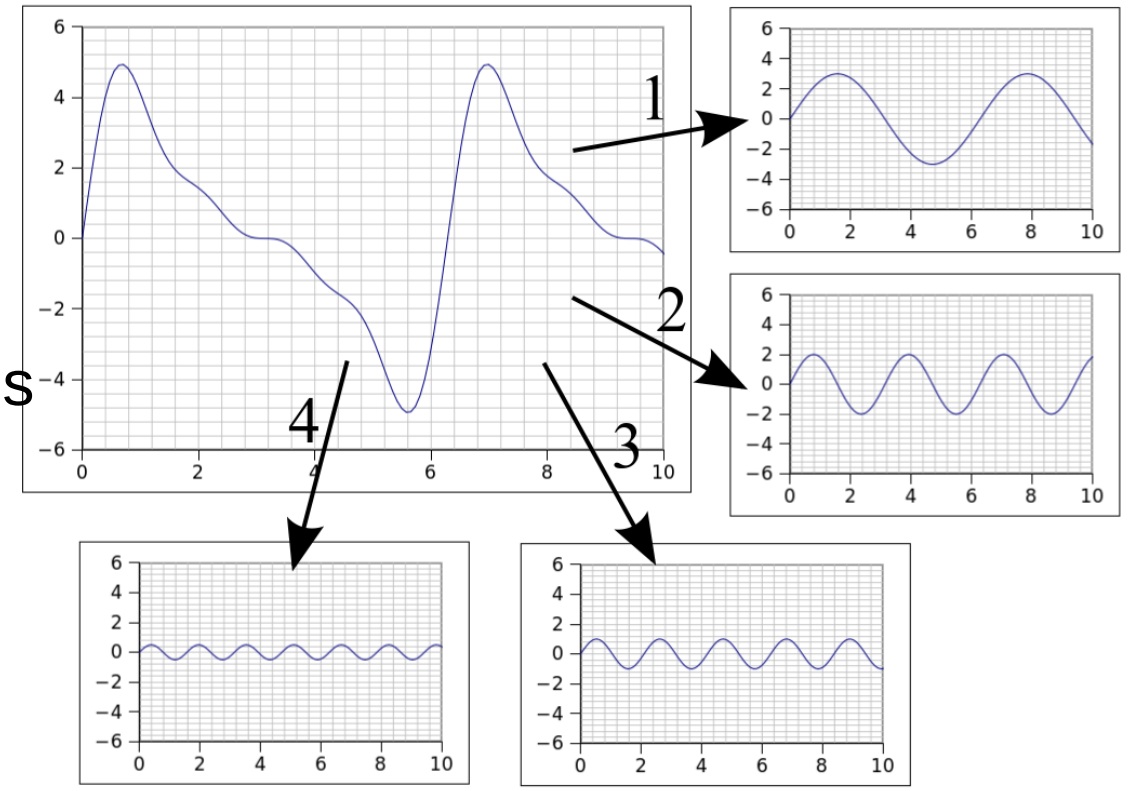
- Analysis of 200 ns trajectory by principal component analysis (PCA)

$$\mathbf{F} = \left\langle \mathbf{M}^{1/2} \left(\mathbf{x} - \langle \mathbf{x} \rangle \right) \left(\mathbf{M}^{1/2} \left(\mathbf{x} - \langle \mathbf{x} \rangle \right) \right)^{T} \right\rangle$$

- calculate and diagonalize the (mass-weighted) covariance matrix.
- Pulls out key

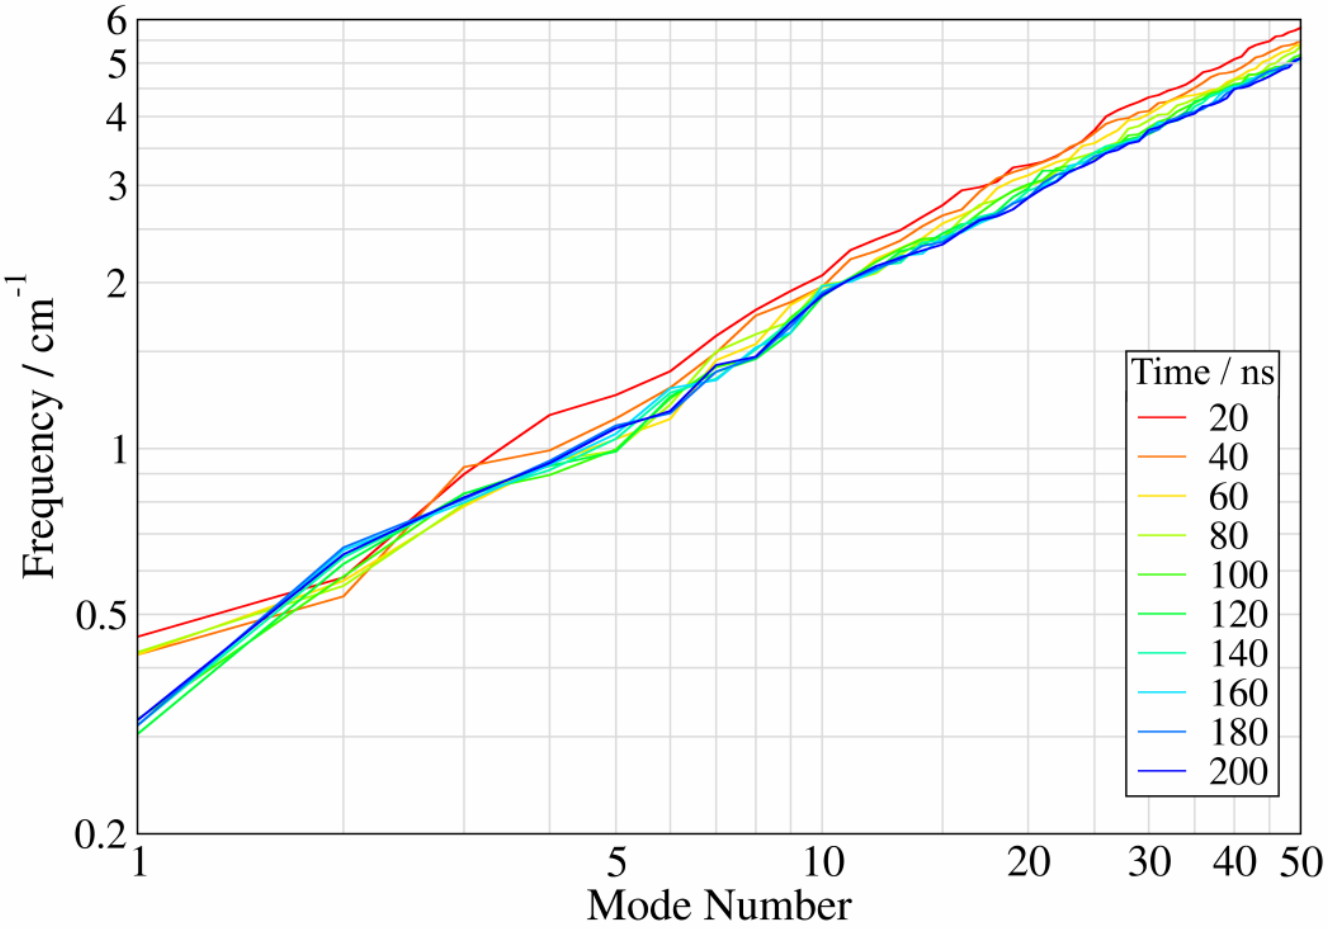
dynamical modes

of motion & frequencies



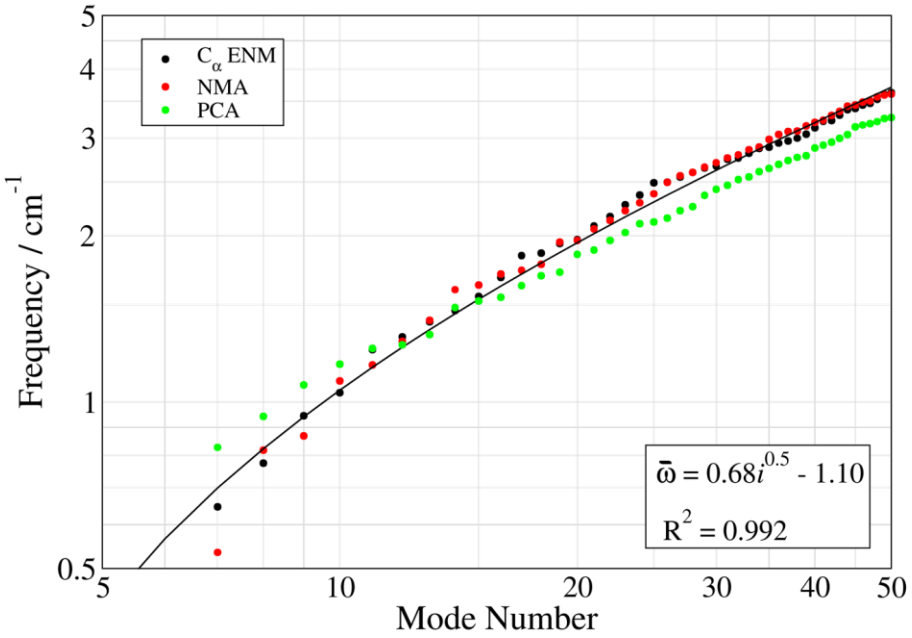
PCA comparison

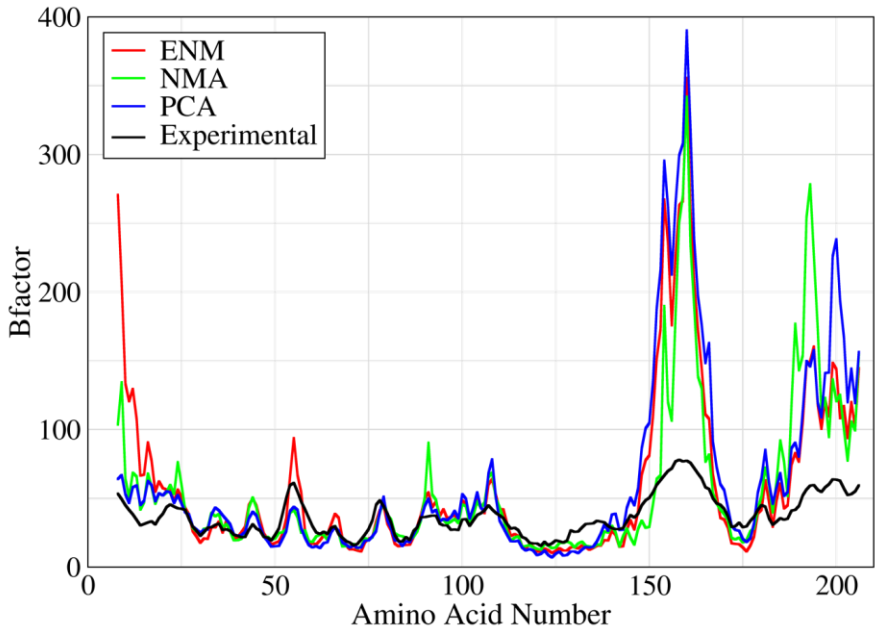
- Test repeatability of analysis



Comparisons

- ENM, PCA, and atomic NMA produce similar frequencies and atomic motions





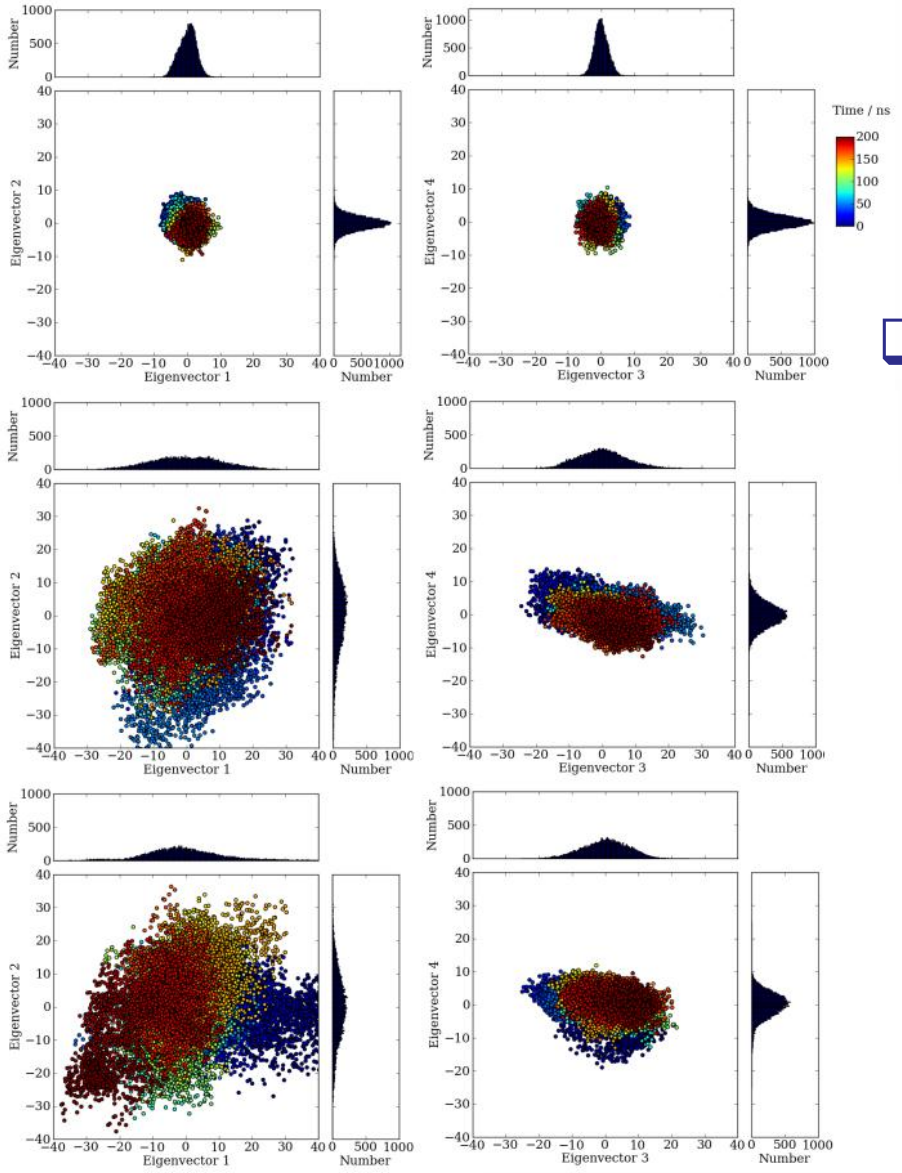
C_α and NMA data scalled to fit PCA data (x0.447)

Motion of protein

apo-CAP

$holo_1$-CAP

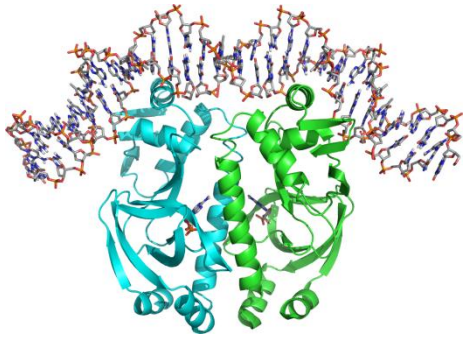
$holo_2$-CAP



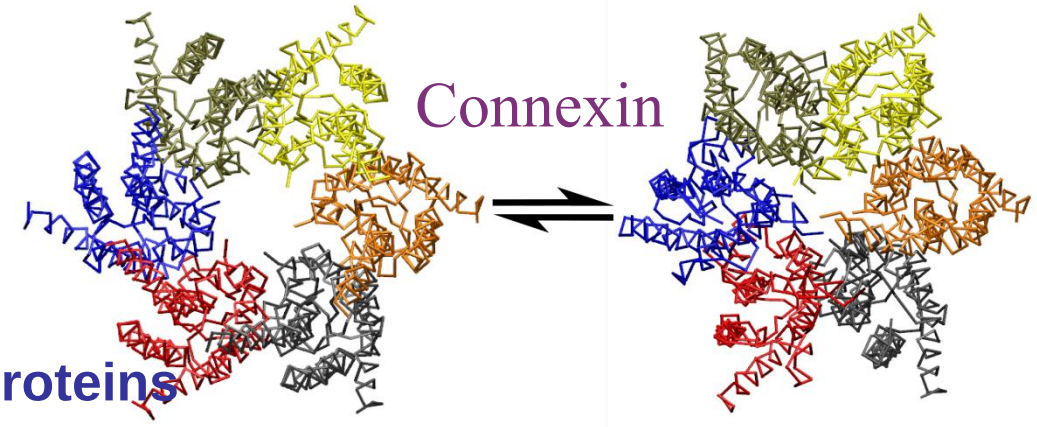
- Protein dynamics changes on ligand binding

Final ideas

- Allosteric binding modelled at different levels suggests proteins may have evolved to harness dynamic pathways
- Also shown for LacR, GlxR (larger effects)
- Possibility of studying dynamic contribution to DNA binding



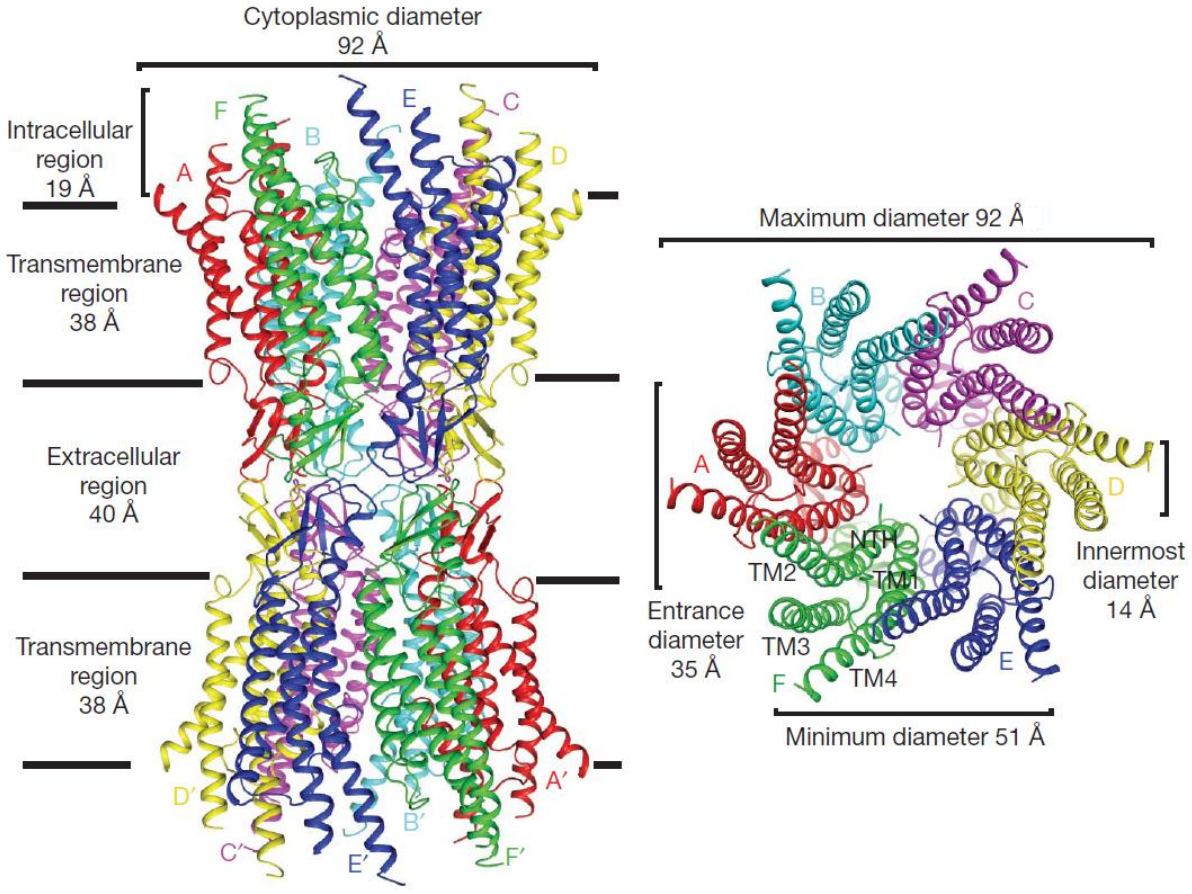
CAP/DNA



- Also see how dynamics is of key importance for other proteins

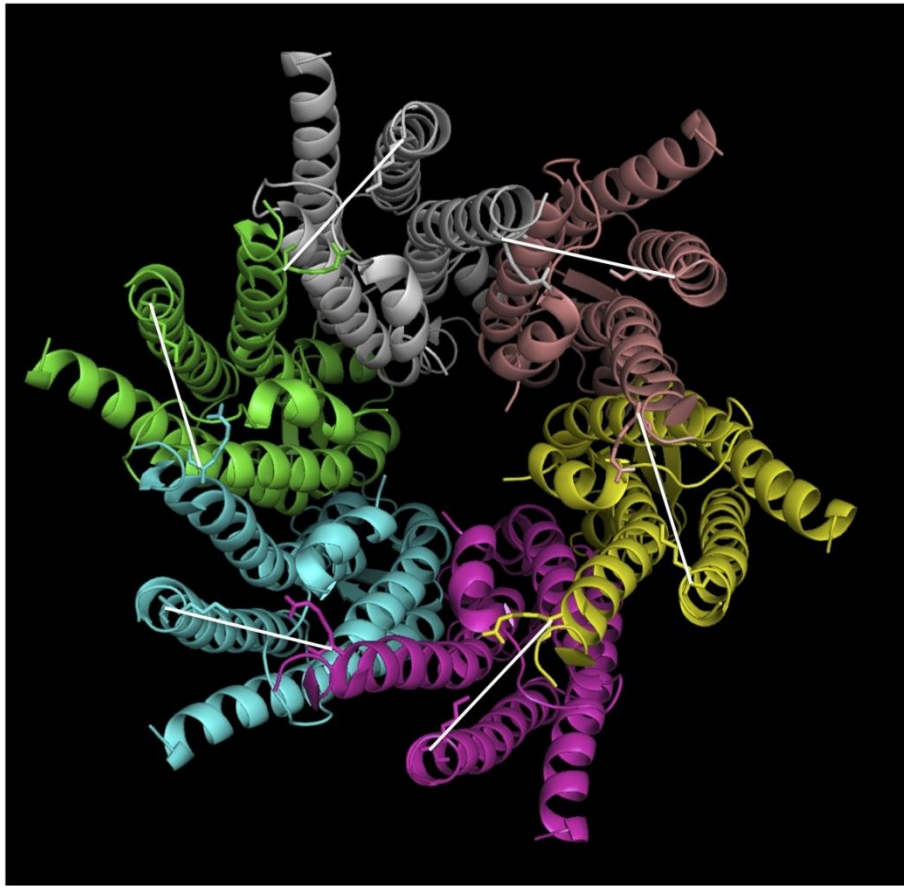
Connexin 26 (a gap junction protein)

- 6 monomers form a funnel pore
- 2 pore units form the inter-cellular pathway



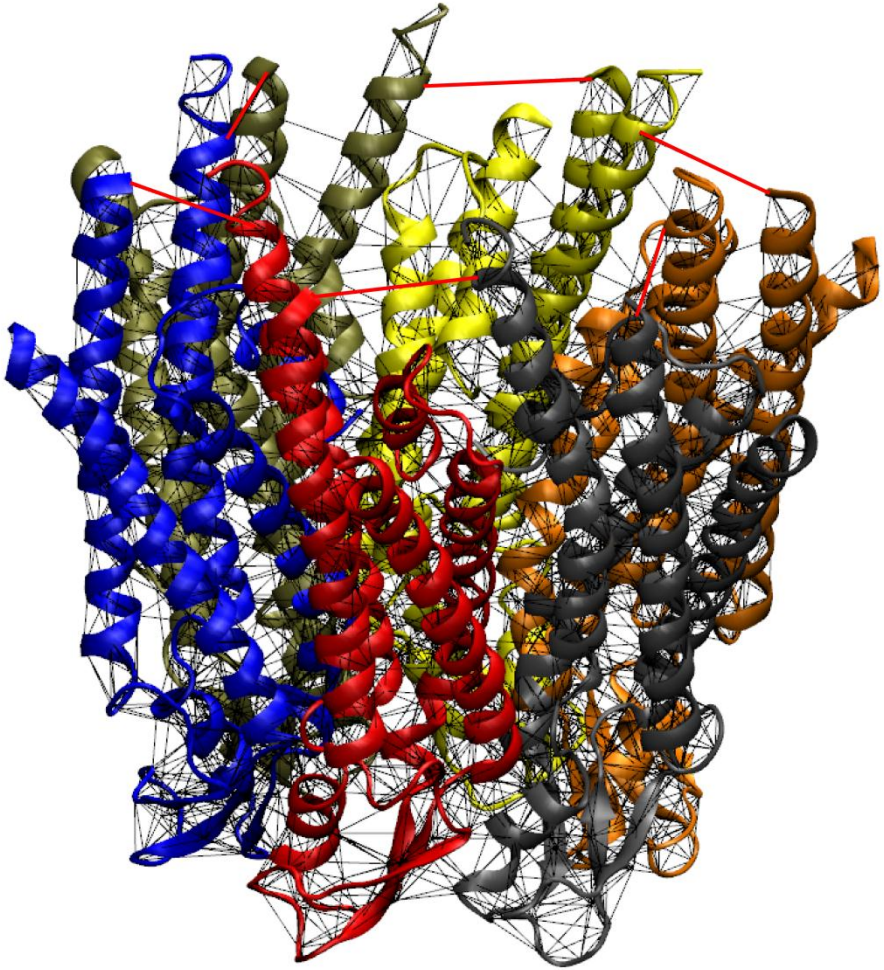
CO_2 binding

- CO_2 binds between monomers at the end of the channel



Connexin ENM

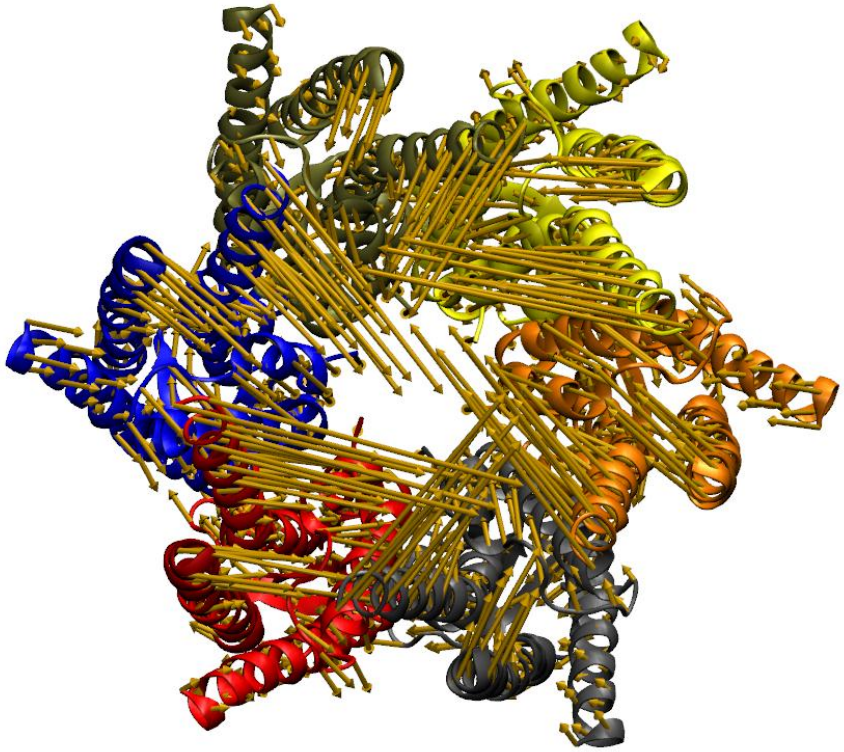
Durham University



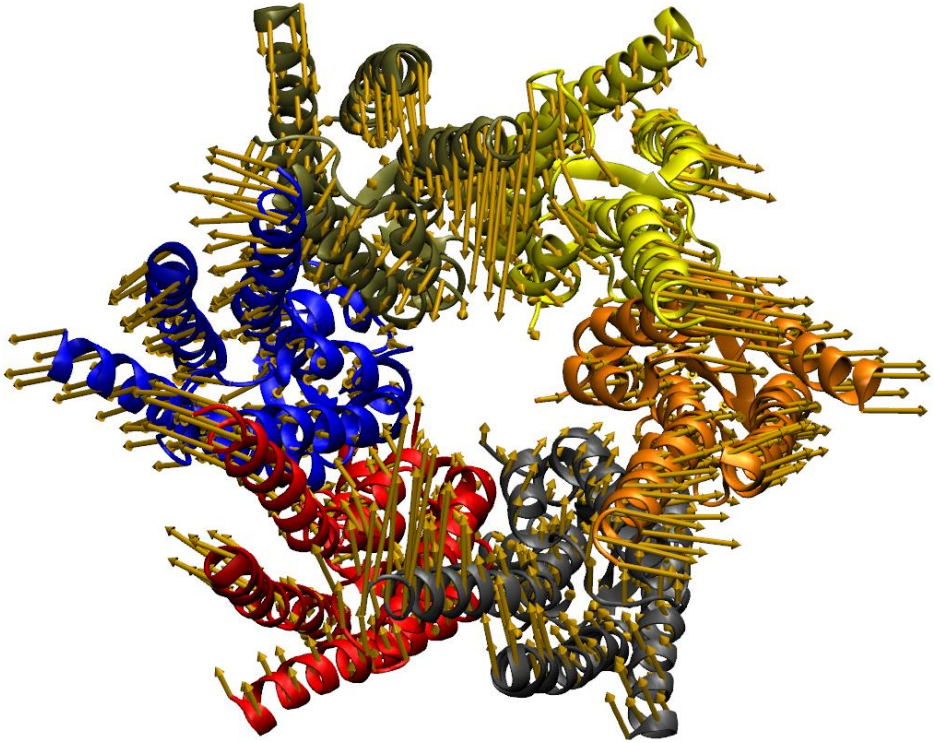
$$V_{ij} = \begin{cases} \frac{k_{ij}}{2}\left(r_{ij} - R_{ij}\right)^2 & R_{ij}^2 \leq R_c^2 \\ 0 & R_{ij}^2 > R_c^2 \end{cases}$$

Variation in Main mode

Durham University



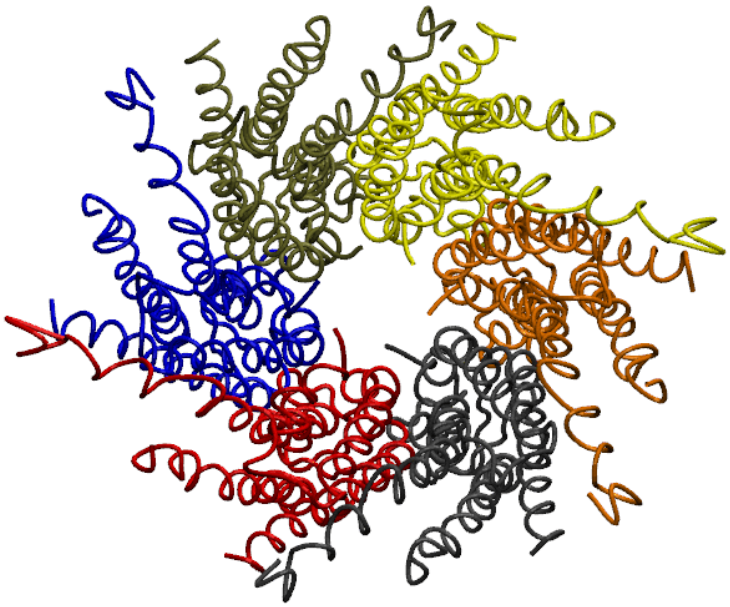
No CO_2



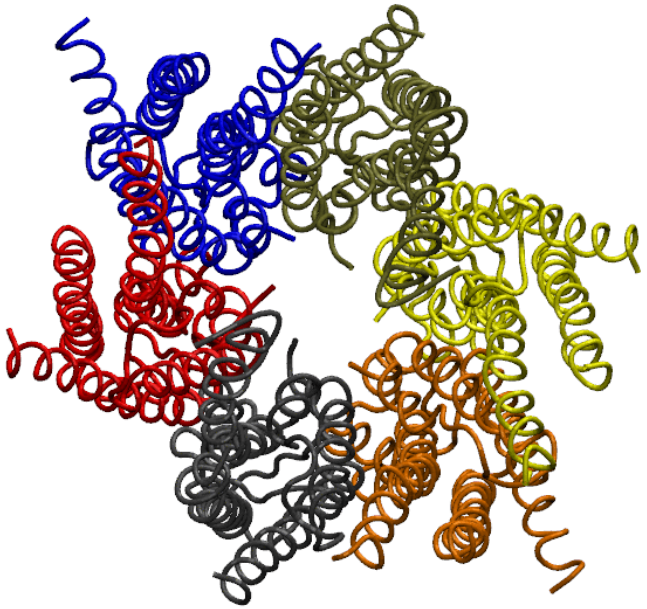
CO_2

Variation in Main mode

Durham University



No CO_2



CO_2

When CO_2 is bound the channel never closes

Summary

- Calculations point to interesting phenomenon "dynamic allostery"
- Thermodynamics basis for this is the vibrational contribution to $\Delta\Delta G$
- Simulations of ENM, super-CG and atomistic models provide valuable insights
- Third site mutation provides a mechanism to control this effect
- Potential for many interesting insights from the role of dynamics in protein function
