The recent developments have shed important new light on the idea that, after the Page time, **interior operators** can be expressed as **acting on the radiation**.

The space-time reason why this is *in principle* possible is that the interior and exterior regions are related via an exponentially large boost. — ’t Hooft

The fact that interior operators can *in principle* be expressed as radiation operators is equivalent to the statement of **black hole complementarity**.
Different microscopic observables that are space-like separated on a Cauchy surface $\Sigma$, but have support on matter field configurations that, when propagated back in time, have collided with macroscopically large center of mass energies, are not simultaneously contained as commuting operators in the physical Hilbert space. Instead such operators are complementary.

`Space Time Complementarity`
The recent developments have shed new light on the idea that, after the Page time, interior operators can be expressed as acting on the radiation.

The space-time reason for why this is possible is that the interior and exterior regions are related via an exponentially large boost. ’t Hooft

The fact that interior operators can in principle be expressed as radiation operators is equivalent to the statement of black hole complementarity.

The microscopic reason or why this is possible is that black evaporation is an **ergodic process** that produces an **random embedding** of the initial state into the Hilbert space of the radiation. Hayden, Preskill

**Approximate quantum error correction** techniques can be used to give an explicit construction of interior operators within a code subspace*. VV, ADH, Yoshida, Penington
Let’s model the black hole formation and evaporation process via AdS/CFT + bath. It maps the initial matter state into a randomly entangled state of CFT and Rad

\[
U \langle \Psi |_{\text{Mat}} = \sum_a |\psi_a \rangle_{\text{CFT}} |a \rangle_{\text{Rad}} = \sum_n |n \rangle_{\text{CFT}} |\phi_n \rangle_{\text{Rad}}
\]

It is then possible to reconstruct the Island operators with exponential accuracy, provided that we are in the post-Page regime

\[
\epsilon = e^{S_{\text{Mat}} + S_{\text{CFT}} - S_{\text{Rad}}} \ll 1
\]

\[\text{Code subspace} \gg \mathcal{H}_{\text{QFT}}\]
The $C_n$ are called Krauss operators. They define a random embedding of Mat into Rad.

The crucial observation that allows for the reconstruction of interior operators is that

$$C_m \dagger C_n \sim p_n \delta_{mn} \mathbb{1}_{\text{Mat}}.$$
The Kraus matrices are microscopically determined* random matrices, drawn from a statistical matrix ensemble:

\[
\sum_b C_{nb}^{*i} C_{bm}^j = p_n \delta_{nm} \delta^{ij} + s_{nm}^{ij}
\]

\[
\sum_n C_{an}^i C_{nb}^{*j} = q_a \delta_{ab} \delta^{ij} + r_{ab}^{ij}
\]

\[
\sum_n p_n = 1
\]

\[
\sum_a q_a = 1
\]
The density matrices of CFT and Rad are given by the product of two $C$-matrices

$$
\rho_{\text{CFT}} = C^\dagger C ; \quad \rho_{\text{Rad}} = C C^\dagger
$$

Coarse graining (phase or ensemble averaging) amounts to performing a Wick contraction

$$
\overline{\rho_{\text{CFT}}} = \sum_{E} p_{E} \mathbb{1}_{\text{CFT}}(M - E)
$$

$$
\overline{\rho_{\text{Rad}}} = \sum_{E} q_{E} \mathbb{1}_{\text{Rad}}(E)
$$
$$\text{tr}(\rho_{\text{CFT}}^2) = \text{tr}(C C^\dagger C C^\dagger) = C C^\dagger C C^\dagger + C C^\dagger C C^\dagger$$

$$= \begin{array}{c}
\text{blue}\end{array} + \begin{array}{c}
\text{red}\end{array} = \sum_E \left(q_E^2 + q_E p_E\right)$$

$$\text{tr}(\rho_{\text{CFT}}^n) = \sum_{E} \sum_{m=0}^{n-1} N(n, m) q_E^{n-m} p_E^m$$
The active ingredient in the construction of interior operators is the recovery operator $R$. It acts on the radiation and on an ancillary CFT, and effectively inverts the time evolution.

Importantly, it does so by employing an **entanglement swap**: after the recovery, the CFT and ancilla CFT are in a thermo-field double state:

$$\langle \Psi \rangle_{\text{Mat}}$$
In formulas:

\[ R |\Phi\rangle_{\text{Rad}} |0\rangle_{\text{CFT}} = \sum_n R_n |\Phi\rangle_{\text{Rad}} |n\rangle_{\text{CFT}} \]

\[ RU |\Psi\rangle_{\text{Mat}} |0\rangle |\tilde{0}\rangle \simeq |\Psi\rangle_{\text{Mat}} |\text{TFD}\rangle \]

\[ |\text{TFD}\rangle = \sum_n \sqrt{p_n} |n\rangle_{\text{CFT}} |n\rangle_{\tilde{\text{CFT}}} \]

- How do we construct this recovery operator?
- And what is it good for?
In formula and pictures:

\[ R \ket{\Phi}_{\text{Rad}} \ket{0}_{\text{CFT}} \sim \sum_n R_n \ket{\Phi}_{\text{Rad}} \ket{n}_{\text{CFT}} \]

\[ R_n = \frac{1}{\sqrt{p_n}} \sigma_{\text{Rad}} \tilde{C}_{\text{Rad}}^{1/2} \]

\[ \sigma_{\text{Rad}} = \sum_n R_n^\dagger \sigma_{\text{Mat}} \tilde{C}^{\dagger} \delta_{nm} \sum_n C_n \tilde{C}^\dagger_n \]

- How do we construct the recovery operator?
We like to use the recovery operators not just for the maximally mixed state, but also in quantum information terminology, this mapping from the initial matter state to the radiation into an approximately pure state. What happens to the quantum entanglement between the CFT and the radiation? It is for this reason that one needs to introduce an ancilla. After this preparation, it now becomes straightforward to return to the recovery map and give the density matrix of the protocol used in [22] for pre-Page time black holes and will be a variant of the Petz map formula and pictures:

\[ R |\Phi\rangle_{\text{Rad}} |0\rangle_{\text{CFT}} = \sum_n R_n |\Phi\rangle_{\text{Rad}} |n\rangle_{\text{CFT}} \]

\[ R_n \approx \frac{1}{\sqrt{p_n}} C_n^\dagger \]

\[ R_n R_m^\dagger \approx \delta_{nm} \mathbb{1}_{\text{Mat}} \]

- How do we construct the recovery operator?
Here we write an approximate sign, which means that this equation holds up to terms that replace the factor verifies that the original state is recovered through an exact relation

‡

To determine the factor of proportionality we proceed as before, and require that the recovery where

We now have all the ingredients to derive the entanglement wedge reconstruction of the

What is it good for?

Reconstruction of interior operators:

In formulas:

\[
R |\Phi\rangle_{\text{Rad}} |0\rangle_{\text{CFT}} \approx \sum_n R_n |\Phi\rangle_{\text{Rad}} |n\rangle_{\text{CFT}}
\]

\[
O^\text{R} \text{Mat} = \langle \tilde{0} | R^\dagger O \text{Mat} R |\tilde{0}\rangle = \sum_n R_n^\dagger O \text{Mat} R_n
\]

\[
O^\text{R} \text{QFT} = \langle \tilde{0} | R^\dagger \tilde{O}^{\text{HKLL}} \text{QFT} R |\tilde{0}\rangle = \sum_{n,m} R_n^\dagger (\tilde{O}^{\text{HKLL}} \text{QFT})_{nm} R_m
\]
In pictures:

\[ \text{tr}(\rho \phi_a(y) \phi_b(x)) = \langle \text{tfd} | \phi_a(y) \phi_b(x) | \text{tfd} \rangle, \]
Suppose we make the ancilla real. Alice and Bob want to arrange a Rendez-Vous on the Island with the help of the powerful quantum supercomputer owned by Bob’s uncle Charlie. Will they succeed?
Charlie is still worried: the black hole still evaporates and the TFD state decoheres.

He wants to find out if Alice and Bob were able to meet:

\[
\begin{align*}
|\Psi\rangle_{\text{Code}} &= \tilde{O}_{\text{Alice}} \mathcal{O}_{\text{Bob}} |\text{tfd}\rangle_{\text{QFT}} \\
R \ U |\Psi\rangle_{\text{Code}} |0\rangle_{\text{Rad}} |0\rangle_{\text{Rad}} &\simeq |\Psi\rangle_{\text{Code}} \otimes |\text{TFD}\rangle \otimes |	ext{TFD}\rangle
\end{align*}
\]
Figure 1: Spatial slice of the two-sided black hole with an elongated ER bridge. The CFTs are entangled with the radiation and are in a mixed state. The ER bridge is now contained inside the new Island and the state Alice and Bob can be reconstructed via the radiation.
\[(O_1)^R (O_2)^R = (O_1 O_2)^R + \text{Error}\]

\[\text{Error} = \epsilon \text{tr}_{\text{CFT}}(O_1 O_2 e^{\beta H})\]

The reconstructed Island operator algebra has a finite ‘unrecoverable error’.

These error terms are responsible for the transfer of information to the exterior.
• Reconstruction of interior operators in terms of the radiation uses that black evaporation produces an **random embedding** of the initial state into the Hilbert space of the radiation.

• This construction is largely state independent, but requires the introduction of a code subspace with entropy $S_{\text{code}}$ such that

$$S_{\text{Mat}} + S_{\text{QFT}}(t) \lesssim S_{\text{Code}} < S_{\text{Rad}}(t) - S_{\text{CFT}}(t)$$

• No ensemble average is needed for reconstruction of interior operators: gravity only knows the ensemble, because it’s a coarse grained description.

• Replica wormholes may provide crucial insight into how QFT breaks down and into the possible mechanism for information transfer to the exterior.
